

APPENDIX A. ATSDR MINIMAL RISK LEVELS AND WORKSHEETS

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) [42 U.S.C. 9601 et seq.], as amended by the Superfund Amendments and Reauthorization Act (SARA) [Pub. L. 99–499], requires that the Agency for Toxic Substances and Disease Registry (ATSDR) develop jointly with the U.S. Environmental Protection Agency (EPA), in order of priority, a list of hazardous substances most commonly found at facilities on the CERCLA National Priorities List (NPL); prepare toxicological profiles for each substance included on the priority list of hazardous substances; and assure the initiation of a research program to fill identified data needs associated with the substances.

The toxicological profiles include an examination, summary, and interpretation of available toxicological information and epidemiologic evaluations of a hazardous substance. During the development of toxicological profiles, Minimal Risk Levels (MRLs) are derived when reliable and sufficient data exist to identify the target organ(s) of effect or the most sensitive health effect(s) for a specific duration for a given route of exposure. An MRL is an estimate of the daily human exposure to a hazardous substance that is likely to be without appreciable risk of adverse noncancer health effects over a specified duration of exposure. MRLs are based on noncancer health effects only and are not based on a consideration of cancer effects. These substance-specific estimates, which are intended to serve as screening levels, are used by ATSDR health assessors to identify contaminants and potential health effects that may be of concern at hazardous waste sites. It is important to note that MRLs are not intended to define clean-up or action levels.

MRLs are derived for hazardous substances using the no-observed-adverse-effect level/uncertainty factor approach. They are below levels that might cause adverse health effects in the people most sensitive to such chemical-induced effects. MRLs are derived for acute (1–14 days), intermediate (15–364 days), and chronic (365 days and longer) durations and for the oral and inhalation routes of exposure. Currently, MRLs for the dermal route of exposure are not derived because ATSDR has not yet identified a method suitable for this route of exposure. MRLs are generally based on the most sensitive chemical-induced end point considered to be of relevance to humans. Serious health effects (such as irreparable damage to the liver or kidneys, or birth defects) are not used as a basis for establishing MRLs. Exposure to a level above the MRL does not mean that adverse health effects will occur.

MRLs are intended only to serve as a screening tool to help public health professionals decide where to look more closely. They may also be viewed as a mechanism to identify those hazardous waste sites that

APPENDIX A

are not expected to cause adverse health effects. Most MRLs contain a degree of uncertainty because of the lack of precise toxicological information on the people who might be most sensitive (e.g., infants, elderly, nutritionally or immunologically compromised) to the effects of hazardous substances. ATSDR uses a conservative (i.e., protective) approach to address this uncertainty consistent with the public health principle of prevention. Although human data are preferred, MRLs often must be based on animal studies because relevant human studies are lacking. In the absence of evidence to the contrary, ATSDR assumes that humans are more sensitive to the effects of hazardous substance than animals and that certain persons may be particularly sensitive. Thus, the resulting MRL may be as much as 100-fold below levels that have been shown to be nontoxic in laboratory animals.

Proposed MRLs undergo a rigorous review process: Health Effects/MRL Workgroup reviews within the Division of Toxicology and Human Health Sciences, expert panel peer reviews, and agency-wide MRL Workgroup reviews, with participation from other federal agencies and comments from the public. They are subject to change as new information becomes available concomitant with updating the toxicological profiles. Thus, MRLs in the most recent toxicological profiles supersede previously published levels. For additional information regarding MRLs, please contact the Division of Toxicology and Human Health Sciences, Agency for Toxic Substances and Disease Registry, 1600 Clifton Road NE, Mailstop F-57, Atlanta, Georgia 30333.

APPENDIX A

MINIMAL RISK LEVEL (MRL) WORKSHEET

Chemical Name: Toxaphene
CAS Numbers: 8001-35-2
Date: May 2014
Profile Status: Final Post-Public Comment
Route: Inhalation Oral
Duration: Acute Intermediate Chronic
Graph Key: 26
Species: Dog

Minimal Risk Level: 0.05 mg/kg/day ppm

Reference: Chu I, Villeneuve DC, Sun CW, et al. 1986. Toxicity of toxaphene in the rat and beagle dog. *Fundam Appl Toxicol* 7:406-418.

Experimental design: (human study details or strain, number of animals per exposure/control group, sex, dose administration details): Groups of male and female beagle dogs (6/sex/group) were given gelatin capsules containing toxaphene at 0, 0.2, 2.0, or 5.0 mg/kg daily for 13 weeks. During the first 2 treatment days, the high-dose group received toxaphene at 10 mg/kg/day. This dose was reduced to 5 mg/kg/day on treatment day 3 because the 10 mg/kg/day dose level elicited convulsions, salivation, and vomiting in 1/6 males and 2/6 females. These clinical signs were not observed in any of the toxaphene-treated dogs throughout the remainder of the scheduled 13-week treatment period.

Effect noted in study and corresponding doses: Serious neurological effects (convulsions, salivation, and vomiting in 1/6 males and 2/6 females) were elicited during the first 2 days of oral treatment at 10 mg/kg/day. These effects were not elicited after the highest dose was reduced to 5 mg/kg/day on treatment day 3 and maintained at that level throughout the remainder of the scheduled 13-week treatment period.

Dose and end point used for MRL derivation: NOAEL of 5 mg/kg/day for neurological effects; the LOAEL was 10 mg/kg/day for clinical signs (convulsions, salivation, and vomiting in 1/6 males and 2/6 females). Support for a NOAEL of 5 mg/kg/day for neurological effects is provided by the results of another dog study in which a single 5 mg/kg dose of toxaphene elicited no clinical signs of neurotoxicity, whereas a single 10 mg/kg dose resulted in convulsions (Lackey 1949). Although both studies identified a serious LOAEL of 10 mg/kg/day for neurological effects, the NOAEL of 5 mg/kg/day (identified in both studies) is considered adequate basis for deriving an acute-duration oral MRL for toxaphene.

NOAEL LOAEL

Uncertainty Factors used in MRL derivation:

- 10 for use of a LOAEL
- 10 for extrapolation from animals to humans
- 10 for human variability

Was a conversion factor used from ppm in food or water to a mg/body weight dose? No.

If an inhalation study in animals, list conversion factors used in determining human equivalent dose: Not applicable.

Was a conversion used from intermittent to continuous exposure? No.

APPENDIX A

Other additional studies or pertinent information that lend support to this MRL: Lackey (1949) reported convulsions in 4/5 fasted dogs administered toxaphene (in corn oil) once by capsule at 10 mg/kg. Higher single dose levels (15–50 mg/kg) resulted in convulsions and mortalities; there were no signs of convulsions in three dogs dosed at 5 mg/kg. Seriously depressed maternal weight gain in pregnant rats and mice have been observed at toxaphene doses in the range of 15–32 mg/kg/day (Chernoff and Carver 1976; Chernoff et al. 1990). The dose necessary to induce nonfatal convulsions in humans has been estimated to be approximately 10 mg/kg (CDC 1963).

APPENDIX A

MINIMAL RISK LEVEL (MRL) WORKSHEET

Chemical Name: Toxaphene
CAS Numbers: 8001-35-2
Date: May 2014
Profile Status: Final Draft Post-Public Comment
Route: Inhalation Oral
Duration: Acute Intermediate Chronic
Graph Key: 47
Species: Monkey

Minimal Risk Level: 0.002 mg/kg/day ppm

Reference: Tryphonas H, Arnold DL, Bryce F, et al. 2001. Effects of toxaphene on the immune system of cynomolgus (*Macaca fascicularis*) monkeys. Food Chem Toxicol 39:947-958.

Experimental design: (human study details or strain, number of animals per exposure/control group, sex, dose administration details): Groups of 10 female cynomolgus monkeys/dose group (approximately 7 years of age on average) were administered toxaphene by oral capsules at 0, 0.1, 0.4, or 0.8 mg/kg/day for up to 75 weeks. Groups of five males were similarly dosed at 0 or 0.8 mg/kg/day (approximately 12.5 and 6 years of age on average, respectively). Testing for immune effects was initiated on week 33 and included flow cytometry, lymphocyte transformation, natural killer cell activity, and determination of serum cortisol during weeks 33–46 and immunizations with SRBC at treatment week 44 a primary response and week 48 for a secondary response (observations made through treatment week 52).

Effect noted in study and corresponding doses: Treatment with toxaphene at 0.4 mg/kg/day resulted in significant ($p < 0.05$) reductions in mean primary anti-SRBC IgM responses at weeks 1 and 4 following primary immunization (27 and 35% lower than that of controls) and secondary anti-SRBC IgM responses at week 1 following secondary immunization (10% lower than that of controls). The dose level of 0.8 mg/kg/day resulted in significantly reduced mean primary anti-SRBC IgM responses at weeks 1–4 following primary immunization, significantly reduced mean secondary anti SRBC IgM response at weeks 1 and 4 following secondary immunization, and significantly reduced primary anti-SRBC IgG responses at weeks 2 and 3 following primary immunization (51 and 43% lower than that of controls). In males, 0.8 mg/kg/day toxaphene induced a significant reduction in mean primary anti-SRBC IgM response at weeks 1–3 following primary immunization. Flow cytometry tests showed that the only effect on leukocyte and lymphocyte subsets was a reduction in absolute B lymphocytes (CD20) in 0.8 mg/kg/day females (62% lower than controls). There were no detectable treatment-related effects on natural killer cell activity, lymphoproliferative response to mitogens, or serum cortisol levels. Table A-1 shows the results of primary anti-SRBC IgM responses.

APPENDIX A

All continuous variable models in the EPA Benchmark Dose Software (Version 2.1.1) were fit to the mean anti-SRBC (IgM) titre data at week 1 post-immunization; standard error values were converted to standard deviation values prior to running the models. A default benchmark response (BMR) of 1 standard deviation (1 SD) from the control mean was selected in the absence of a toxicological rationale for selecting an alternative BMR. Model results for the mean anti-SRBC (IgM) titre data are shown in Table A-2. The linear model was initially fit to the data using constant variance, but failed to meet conventional goodness-of-fit criteria for modeled variance (p=0.04395). Adequate fit for modeled variance was obtained, however, when fit to the data using non-constant variance. Therefore, non-constant variance was selected to fit the remaining continuous variable models to the data. The Hill model failed the test for mean fit (degrees of freedom <0) and was not considered further. Using non-homogeneous variance, the polynomial (2- and 3-degree), and power models converged on the linear model and provided identical predictions of the BMD_{1SD} (0.34 mg/kg/day) and the 95% lower confidence limit on the BMD_{1SD} (BMDL_{1SD}; 0.22 mg/kg/day). The fit of the linear model to the malformation data is presented in Figure A-1. This figure is identical to those generated from the polynomial (2- and 3-degree), and power models.

APPENDIX A

Table A-2. Model Predictions for Mean Anti-SRBC (IgM) Titre Data at Week 1 Post-Immunization from Female Cynomolgus Monkeys Administered Toxaphene in Gelatin Capsule Daily for 75 Weeks Including 44 Weeks Prior to Immunization

| Model | Variance p -value ^a | Means p -value ^a | Scaled residual of interest ^b | AIC | BMD _{1SD} (mg/kg/day) | BMDL _{1SD} (mg/kg/day) |

| Hill ^c | 0.48 | NA ^e | 0.26 | 99.68 | 0.14 | 0.04 |

^aValues <0.10 fail to meet conventional goodness-of-fit criteria.

^bScaled residual at measured response closest to the benchmark response.

^cCoefficients restricted to be negative.

^dPower restricted to ≥ 1 .

^eDegrees of freedom for test of mean fit are less than or equal to 0; the χ^2 test for fit is not valid.

AIC = Akaike's Information Criterion; BMD = maximum likelihood estimate of the dose/concentration associated with the selected benchmark response; BMDL = 95% lower confidence limit on the BMD; SD = standard deviation

APPENDIX A

Figure A-1. Predicted and Observed Mean Anti-SRBC (IgM) Titres from Female Cynomolgus Monkeys Administered Toxaphene in Gelatin Capsule Daily for 75 Weeks Including 44 Weeks Prior to Immunization*

*BMD and BMDL associated with 1 standard deviation from the estimated control mean are shown; doses given in units of mg/kg/day.

The linear model form and parameters output from benchmark dose analysis of anti-SRBC titres from female cynomolgus monkeys of the principal study (Tryphonas et al. 2001) follows:

The form of the response function is: $Y[\text{dose}] = \text{beta}_0 + \text{beta}_1 \cdot \text{dose} + \text{beta}_2 \cdot \text{dose}^2 + \dots$

Dependent variable = mean

Independent variable = dose

The polynomial coefficients are restricted to be negative

The variance is to be modeled as $\text{Var}(i) = \exp(\text{lalpha} + \log(\text{mean}(i))) \cdot \text{rho}$

Total number of dose groups = 4

Total number of records with missing values = 0

Maximum number of iterations = 250

Relative Function Convergence has been set to: 1e-008

Parameter Convergence has been set to: 1e-008

Default Initial Parameter Values

lalpha = 1.46271

rho = 0

APPENDIX A

beta_0 = 6.94194
beta_1 = -4.12903

Asymptotic Correlation Matrix of Parameter Estimates

| | lalpha | rho | beta_0 | beta_1 |
|--------|--------|-------|--------|--------|
| lalpha | 1 | -0.99 | -0.077 | 0.2 |
| rho | -0.99 | 1 | 0.076 | -0.2 |
| beta_0 | -0.077 | 0.076 | 1 | -0.6 |
| beta_1 | 0.2 | -0.2 | -0.6 | 1 |

Parameter Estimates 95.0% Wald Confidence Interval

|----------|----------|-----------|-------------------|-------------------|
| lalpha | 4.87328 | 1.76864 | 1.40682 | 8.33975 |
| rho | -2.14694 | 1.03446 | -4.17445 | -0.119432 |
| beta_0 | 6.95256 | 0.342736 | 6.28081 | 7.62431 |
| beta_1 | -4.14011 | 1.02288 | -6.14492 | -2.13531 |

Table of Data and Estimated Values of Interest

| Dose | N | Obs Mean | Est Mean | Obs Std Dev | Est Std Dev | Scaled Res. |
|------|----|----------|----------|-------------|-------------|-------------|
| 0 | 10 | 7.1 | 6.95 | 1.11 | 1.43 | 0.327 |
| 0.1 | 10 | 6.4 | 6.54 | 1.71 | 1.52 | -0.288 |
| 0.4 | 10 | 5.2 | 5.3 | 2.5 | 1.91 | -0.16 |
| 0.8 | 10 | 3.7 | 3.64 | 2.62 | 2.86 | 0.0659 |

Model Descriptions for likelihoods calculated

Model A1: $Y_{ij} = \mu(i) + e_{(ij)}$ $\text{Var}\{e_{(ij)}\} = \sigma^2$

Model A2: $Y_{ij} = \mu(i) + e_{(ij)}$ $\text{Var}\{e_{(ij)}\} = \sigma(i)^2$

Model A3: $Y_{ij} = \mu(i) + e_{(ij)}$ $\text{Var}\{e_{(ij)}\} = \exp(\text{lalpha} + \text{rho} \cdot \ln(\mu(i)))$
Model A3 uses any fixed variance parameters that were specified by the user

Model R: $Y_i = \mu + e(i)$ $\text{Var}\{e(i)\} = \sigma^2$

Likelihoods of Interest

| Model | Log(likelihood) | # Param's | AIC |
|--------|-----------------|-----------|------------|
| A1 | -47.147015 | 5 | 104.294030 |
| A2 | -43.095974 | 8 | 102.191948 |
| A3 | -43.837856 | 6 | 99.675711 |
| fitted | -44.727388 | 4 | 97.454776 |
| R | -54.279147 | 2 | 112.558295 |

Explanation of Tests

Test 1: Do responses and/or variances differ among Dose levels? (A2 vs. R)
Test 2: Are Variances Homogeneous? (A1 vs A2)
Test 3: Are variances adequately modeled? (A2 vs. A3)

APPENDIX A

Test 4: Does the Model for the Mean Fit? (A3 vs. fitted)

(Note: When rho=0 the results of Test 3 and Test 2 will be the same.)

Tests of Interest

| Test | -2*log(Likelihood Ratio) | Test df | p-value |
|--------|--------------------------|---------|----------|
| Test 1 | 22.3663 | 6 | 0.001039 |
| Test 2 | 8.10208 | 3 | 0.04395 |
| Test 3 | 1.48376 | 2 | 0.4762 |
| Test 4 | 1.77906 | 2 | 0.4108 |

The p-value for Test 1 is less than .05. There appears to be a difference between response and/or variances among the dose levels. It seems appropriate to model the data

The p-value for Test 2 is less than .1. A non-homogeneous variance model appears to be appropriate

The p-value for Test 3 is greater than .1. The modeled variance appears to be appropriate here

The p-value for Test 4 is greater than .1. The model chosen seems to adequately describe the data

Benchmark Dose Computation

Specified effect = 1
 Risk Type = Estimated standard deviations from the control mean
 Confidence level = 0.95
 BMD = 0.3445
 BMDL = 0.219859

Dose and end point used for MRL derivation: A BMDL_{1SD} of 0.22 mg/kg/day for decreased anti-SRBC (IgM) titers as an indicator of decreased humoral immunity.

NOAEL LOAEL BMD

Uncertainty Factors used in MRL derivation:

10 for use of a LOAEL
 10 for extrapolation from animals to humans
 10 for human variability

Was a conversion factor used from ppm in food or water to a mg/body weight dose? No.

If an inhalation study in animals, list conversion factors used in determining human equivalent dose: Not applicable.

Was a conversion used from intermittent to continuous exposure? No.

APPENDIX A

Other additional studies or pertinent information that lend support to this MRL: In an enzyme-linked immunosorbent assay (ELISA) performed on female mice that received toxaphene from the diet at doses ≥ 19 mg/kg/day for up to 8 weeks, Allen et al. (1983) reported suppressed antibody production, indicating depressed humoral immunity; the study identified a NOAEL of 2 mg/kg/day for the effect. Koller et al. (1983) reported a 46% decrease in the IgG primary antibody response in male rats receiving toxaphene from the diet at 2.6 mg/kg/day for up to 9 weeks and challenged twice (after 8 and 15 days on test) with keyhole limpet hemocyanin (KLH).

APPENDIX B. USER'S GUIDE

Chapter 1

Public Health Statement

This chapter of the profile is a health effects summary written in non-technical language. Its intended audience is the general public, especially people living in the vicinity of a hazardous waste site or chemical release. If the Public Health Statement were removed from the rest of the document, it would still communicate to the lay public essential information about the chemical.

The major headings in the Public Health Statement are useful to find specific topics of concern. The topics are written in a question and answer format. The answer to each question includes a sentence that will direct the reader to chapters in the profile that will provide more information on the given topic.

Chapter 2

Relevance to Public Health

This chapter provides a health effects summary based on evaluations of existing toxicologic, epidemiologic, and toxicokinetic information. This summary is designed to present interpretive, weight-of-evidence discussions for human health end points by addressing the following questions:

1. What effects are known to occur in humans?
2. What effects observed in animals are likely to be of concern to humans?
3. What exposure conditions are likely to be of concern to humans, especially around hazardous waste sites?

The chapter covers end points in the same order that they appear within the Discussion of Health Effects by Route of Exposure section, by route (inhalation, oral, and dermal) and within route by effect. Human data are presented first, then animal data. Both are organized by duration (acute, intermediate, chronic). *In vitro* data and data from parenteral routes (intramuscular, intravenous, subcutaneous, etc.) are also considered in this chapter.

The carcinogenic potential of the profiled substance is qualitatively evaluated, when appropriate, using existing toxicokinetic, genotoxic, and carcinogenic data. ATSDR does not currently assess cancer potency or perform cancer risk assessments. Minimal Risk Levels (MRLs) for noncancer end points (if derived) and the end points from which they were derived are indicated and discussed.

Limitations to existing scientific literature that prevent a satisfactory evaluation of the relevance to public health are identified in the Chapter 3 Data Needs section.

Interpretation of Minimal Risk Levels

Where sufficient toxicologic information is available, ATSDR has derived MRLs for inhalation and oral routes of entry at each duration of exposure (acute, intermediate, and chronic). These MRLs are not meant to support regulatory action, but to acquaint health professionals with exposure levels at which adverse health effects are not expected to occur in humans.

APPENDIX B

MRLs should help physicians and public health officials determine the safety of a community living near a chemical emission, given the concentration of a contaminant in air or the estimated daily dose in water. MRLs are based largely on toxicological studies in animals and on reports of human occupational exposure.

MRL users should be familiar with the toxicologic information on which the number is based. Chapter 2, "Relevance to Public Health," contains basic information known about the substance. Other sections such as Chapter 3 Section 3.9, "Interactions with Other Substances," and Section 3.10, "Populations that are Unusually Susceptible" provide important supplemental information.

MRL users should also understand the MRL derivation methodology. MRLs are derived using a modified version of the risk assessment methodology that the Environmental Protection Agency (EPA) provides (Barnes and Dourson 1988) to determine reference doses (RfDs) for lifetime exposure.

To derive an MRL, ATSDR generally selects the most sensitive end point which, in its best judgement, represents the most sensitive human health effect for a given exposure route and duration. ATSDR cannot make this judgement or derive an MRL unless information (quantitative or qualitative) is available for all potential systemic, neurological, and developmental effects. If this information and reliable quantitative data on the chosen end point are available, ATSDR derives an MRL using the most sensitive species (when information from multiple species is available) with the highest no-observed-adverse-effect level (NOAEL) that does not exceed any adverse effect levels. When a NOAEL is not available, a lowest-observed-adverse-effect level (LOAEL) can be used to derive an MRL, and an uncertainty factor (UF) of 10 must be employed. Additional uncertainty factors of 10 must be used both for human variability to protect sensitive subpopulations (people who are most susceptible to the health effects caused by the substance) and for interspecies variability (extrapolation from animals to humans). In deriving an MRL, these individual uncertainty factors are multiplied together. The product is then divided into the inhalation concentration or oral dosage selected from the study. Uncertainty factors used in developing a substance-specific MRL are provided in the footnotes of the levels of significant exposure (LSE) tables.

Chapter 3

Health Effects

Tables and Figures for Levels of Significant Exposure (LSE)

Tables and figures are used to summarize health effects and illustrate graphically levels of exposure associated with those effects. These levels cover health effects observed at increasing dose concentrations and durations, differences in response by species, MRLs to humans for noncancer end points, and EPA's estimated range associated with an upper-bound individual lifetime cancer risk of 1 in 10,000 to 1 in 10,000,000. Use the LSE tables and figures for a quick review of the health effects and to locate data for a specific exposure scenario. The LSE tables and figures should always be used in conjunction with the text. All entries in these tables and figures represent studies that provide reliable, quantitative estimates of NOAELs, LOAELs, or Cancer Effect Levels (CELs).

The legends presented below demonstrate the application of these tables and figures. Representative examples of LSE Table 3-1 and Figure 3-1 are shown. The numbers in the left column of the legends correspond to the numbers in the example table and figure.

APPENDIX B

LEGEND**See Sample LSE Table 3-1 (page B-6)**

- (1) Route of Exposure. One of the first considerations when reviewing the toxicity of a substance using these tables and figures should be the relevant and appropriate route of exposure. Typically when sufficient data exist, three LSE tables and two LSE figures are presented in the document. The three LSE tables present data on the three principal routes of exposure, i.e., inhalation, oral, and dermal (LSE Tables 3-1, 3-2, and 3-3, respectively). LSE figures are limited to the inhalation (LSE Figure 3-1) and oral (LSE Figure 3-2) routes. Not all substances will have data on each route of exposure and will not, therefore, have all five of the tables and figures.
- (2) Exposure Period. Three exposure periods—acute (less than 15 days), intermediate (15–364 days), and chronic (365 days or more)—are presented within each relevant route of exposure. In this example, an inhalation study of intermediate exposure duration is reported. For quick reference to health effects occurring from a known length of exposure, locate the applicable exposure period within the LSE table and figure.
- (3) Health Effect. The major categories of health effects included in LSE tables and figures are death, systemic, immunological, neurological, developmental, reproductive, and cancer. NOAELs and LOAELs can be reported in the tables and figures for all effects but cancer. Systemic effects are further defined in the "System" column of the LSE table (see key number 18).
- (4) Key to Figure. Each key number in the LSE table links study information to one or more data points using the same key number in the corresponding LSE figure. In this example, the study represented by key number 18 has been used to derive a NOAEL and a Less Serious LOAEL (also see the two "18r" data points in sample Figure 3-1).
- (5) Species. The test species, whether animal or human, are identified in this column. Chapter 2, "Relevance to Public Health," covers the relevance of animal data to human toxicity and Section 3.4, "Toxicokinetics," contains any available information on comparative toxicokinetics. Although NOAELs and LOAELs are species specific, the levels are extrapolated to equivalent human doses to derive an MRL.
- (6) Exposure Frequency/Duration. The duration of the study and the weekly and daily exposure regimens are provided in this column. This permits comparison of NOAELs and LOAELs from different studies. In this case (key number 18), rats were exposed to "Chemical x" via inhalation for 6 hours/day, 5 days/week, for 13 weeks. For a more complete review of the dosing regimen, refer to the appropriate sections of the text or the original reference paper (i.e., Nitschke et al. 1981).
- (7) System. This column further defines the systemic effects. These systems include respiratory, cardiovascular, gastrointestinal, hematological, musculoskeletal, hepatic, renal, and dermal/ocular. "Other" refers to any systemic effect (e.g., a decrease in body weight) not covered in these systems. In the example of key number 18, one systemic effect (respiratory) was investigated.
- (8) NOAEL. A NOAEL is the highest exposure level at which no harmful effects were seen in the organ system studied. Key number 18 reports a NOAEL of 3 ppm for the respiratory system, which was used to derive an intermediate exposure, inhalation MRL of 0.005 ppm (see footnote "b").

APPENDIX B

- (9) LOAEL. A LOAEL is the lowest dose used in the study that caused a harmful health effect. LOAELs have been classified into "Less Serious" and "Serious" effects. These distinctions help readers identify the levels of exposure at which adverse health effects first appear and the gradation of effects with increasing dose. A brief description of the specific end point used to quantify the adverse effect accompanies the LOAEL. The respiratory effect reported in key number 18 (hyperplasia) is a Less Serious LOAEL of 10 ppm. MRLs are not derived from Serious LOAELs.
- (10) Reference. The complete reference citation is given in Chapter 9 of the profile.
- (11) CEL. A CEL is the lowest exposure level associated with the onset of carcinogenesis in experimental or epidemiologic studies. CELs are always considered serious effects. The LSE tables and figures do not contain NOAELs for cancer, but the text may report doses not causing measurable cancer increases.
- (12) Footnotes. Explanations of abbreviations or reference notes for data in the LSE tables are found in the footnotes. Footnote "b" indicates that the NOAEL of 3 ppm in key number 18 was used to derive an MRL of 0.005 ppm.

LEGEND**See Sample Figure 3-1 (page B-7)**

LSE figures graphically illustrate the data presented in the corresponding LSE tables. Figures help the reader quickly compare health effects according to exposure concentrations for particular exposure periods.

- (13) Exposure Period. The same exposure periods appear as in the LSE table. In this example, health effects observed within the acute and intermediate exposure periods are illustrated.
- (14) Health Effect. These are the categories of health effects for which reliable quantitative data exists. The same health effects appear in the LSE table.
- (15) Levels of Exposure. Concentrations or doses for each health effect in the LSE tables are graphically displayed in the LSE figures. Exposure concentration or dose is measured on the log scale "y" axis. Inhalation exposure is reported in mg/m³ or ppm and oral exposure is reported in mg/kg/day.
- (16) NOAEL. In this example, the open circle designated 18r identifies a NOAEL critical end point in the rat upon which an intermediate inhalation exposure MRL is based. The key number 18 corresponds to the entry in the LSE table. The dashed descending arrow indicates the extrapolation from the exposure level of 3 ppm (see entry 18 in the table) to the MRL of 0.005 ppm (see footnote "b" in the LSE table).
- (17) CEL. Key number 38m is one of three studies for which CELs were derived. The diamond symbol refers to a CEL for the test species-mouse. The number 38 corresponds to the entry in the LSE table.

APPENDIX B

- (18) Estimated Upper-Bound Human Cancer Risk Levels. This is the range associated with the upper-bound for lifetime cancer risk of 1 in 10,000 to 1 in 10,000,000. These risk levels are derived from the EPA's Human Health Assessment Group's upper-bound estimates of the slope of the cancer dose response curve at low dose levels (q_1^*).
- (19) Key to LSE Figure. The Key explains the abbreviations and symbols used in the figure.

Table 3-1. Levels of Significant Exposure to [Chemical x] – Inhalation

| Key to figure ^a | Species | Exposure frequency/ duration | System | NOAEL (ppm) | LOAEL (effect) | | Reference |
|------------------------------|----------|---------------------------------|-------------------------------|-------------|--------------------|------------------|--|
| | | | | | Less serious (ppm) | Serious (ppm) | |
| INTERMEDIATE EXPOSURE | | | | | | | |
| | 5 | 6 | 7 | 8 | 9 | | 10 |
| 3 → | Systemic | ↓ | ↓ | ↓ | ↓ | ↓ | ↓ |
| 4 → | 18 | Rat | 13 wk 5 d/wk 6 hr/d | Resp | 3 ^b | 10 (hyperplasia) | Nitschke et al. 1981 |
| CHRONIC EXPOSURE | | | | | | | |
| | Cancer | | | | | 11 | |
| | | | | | ↓ | | |
| | 38 | Rat | 18 mo 5 d/wk 7 hr/d | | | 20 | (CEL, multiple organs) Wong et al. 1982 |
| | 39 | Rat | 89–104 wk 5 d/wk 6 hr/d | | | 10 | (CEL, lung tumors, nasal tumors) NTP 1982 |
| | 40 | Mouse | 79–103 wk 5 d/wk 6 hr/d | | | 10 | (CEL, lung tumors, hemangiosarcomas) NTP 1982 |

12 →

^a The number corresponds to entries in Figure 3-1.

^b Used to derive an intermediate inhalation Minimal Risk Level (MRL) of 5×10^{-3} ppm; dose adjusted for intermittent exposure and divided by an uncertainty factor of 100 (10 for extrapolation from animal to humans, 10 for human variability).
