Case Studies in Environmental Medicine (CSEM)

Ethylene Glycol and Propylene Glycol Toxicity

Course: WB 4342
CE Original Date: March 20, 2020
CE Expiration Date: March 20, 2022

Key Concepts

- Ethylene glycol ingestion first affects the central nervous system (CNS). After a characteristic latent period, toxic metabolites might produce signs of inebriation followed by serious illness and even death.
- No studies were located regarding a link between ethylene glycol exposure and cancer or reproductive or developmental hazards in humans.
- Propylene glycol is much less toxic than ethylene glycol.

About This and Other Case Studies in Environmental Medicine

This educational case study is one in a series of self-instructional modules designed to increase the primary care provider’s knowledge of hazardous substances in the environment. The modules also promote adoption of medical practices that aid in the evaluation and care of potentially exposed patients. You can access the complete series of Case Studies in Environmental Medicine on the Agency for Toxic Substances and Disease Registry (ATSDR) website at URL: https://www.atsdr.cdc.gov/emes/health_professionals/index.html.

A downloadable PDF version of this educational series and other environmental medicine materials provides content in an electronic, printable format, especially for those who might lack adequate Internet service.

## How to Use This Course

<table>
<thead>
<tr>
<th><strong>Introduction</strong></th>
<th>Case Studies in Environmental Medicine’s goal is to increase the primary care provider’s knowledge of hazardous substances in the environment and to help in evaluation and treating of potentially exposed patients. This case study focuses on ethylene glycol and propylene glycol toxicity.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Availability</strong></td>
<td>Two versions of the Ethylene Glycol/Propylene Glycol Toxicity CSEM are available.</td>
</tr>
<tr>
<td></td>
<td>• The HTML version (<em>To be added after clearance during Web production</em>) provides content through the Internet.</td>
</tr>
<tr>
<td></td>
<td>• The downloadable PDF version (<em>To be added after clearance during web production</em>) provides content in an electronic, printable format, especially for those who might lack adequate Internet service.</td>
</tr>
<tr>
<td></td>
<td>• The HTML version offers interactive exercises and prescriptive feedback to the user.</td>
</tr>
<tr>
<td><strong>Instructions</strong></td>
<td>Follow these steps to make the most effective use of this course:</td>
</tr>
<tr>
<td></td>
<td>• Take the Initial Check to assess your current knowledge about ethylene glycol and propylene glycol toxicity.</td>
</tr>
<tr>
<td></td>
<td>• Read the title, learning objectives, text, and key points in each section.</td>
</tr>
<tr>
<td></td>
<td>• Complete the progress check exercises at the end of each section and check your answers.</td>
</tr>
<tr>
<td></td>
<td>• Complete and submit your assessment and posttest response online if you want continuing education credit. You can print continuing education certificates immediately after course completion.</td>
</tr>
</tbody>
</table>
### Instructional Format

This course is designed to help you learn efficiently. Topics are clearly labeled; you can skip sections or quickly scan sections with which you are already familiar. This labeling also allows you to use this training material as a handy reference. To help you identify and absorb important content quickly, we’ve structured each section as follows:

<table>
<thead>
<tr>
<th>Section Element</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Serves as a “focus question” you should be able to answer after completing the section</td>
</tr>
<tr>
<td>Learning Objectives</td>
<td>Describes specific content addressed in each section and focuses your attention on important points</td>
</tr>
<tr>
<td>Text</td>
<td>Provides the information you need to answer the focus question(s) and achieve the learning objectives</td>
</tr>
<tr>
<td>Key Points</td>
<td>Highlights important issues and helps you review</td>
</tr>
<tr>
<td>Progress Check Exercises</td>
<td>Enables you to test yourself to determine whether you have mastered the learning objectives</td>
</tr>
<tr>
<td>Progress Check Answers</td>
<td>Provides feedback to ensure you understand the content and can locate information in the text</td>
</tr>
</tbody>
</table>

### Learning Objectives

After completing the Ethylene Glycol and Propylene Glycol CSEM, you will be able to accomplish the following:

<table>
<thead>
<tr>
<th>Content Area</th>
<th>Learning Objectives</th>
</tr>
</thead>
<tbody>
<tr>
<td>What Is Ethylene Glycol?</td>
<td>• Describe the properties of ethylene glycol</td>
</tr>
<tr>
<td>Where Is Ethylene Glycol Found?</td>
<td>• Identify sources of ethylene glycol exposure</td>
</tr>
<tr>
<td>Topic</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>What Are Routes of Exposure to Ethylene Glycol?</td>
<td>Identify the most common route of exposure to ethylene glycol that results in toxicity in the general U.S. population</td>
</tr>
<tr>
<td>Who Is at Risk of Exposure to Ethylene Glycol?</td>
<td>Identify who is at risk of exposure to ethylene glycol</td>
</tr>
<tr>
<td>What Is the Biologic Fate of Ethylene Glycol?</td>
<td>Explain the major pathway of ethylene glycol metabolism in the body</td>
</tr>
<tr>
<td>What Are the Toxicological Effects of Ethylene Glycol Poisoning?</td>
<td>Describe the toxicological effects of ethylene glycol poisoning.</td>
</tr>
<tr>
<td>Clinical Assessment – History and Physical Exam</td>
<td>Describe what is included in the initial history and physical examination of patients potentially exposed to ethylene glycol</td>
</tr>
<tr>
<td></td>
<td>Describe how the clinical presentation changes over time</td>
</tr>
<tr>
<td>Clinical Assessment - Laboratory Tests</td>
<td>Identify the abnormal laboratory findings associated with ethylene glycol poisoning</td>
</tr>
<tr>
<td></td>
<td>List three measurements that can assist with diagnosis of ethylene glycol poisoning</td>
</tr>
<tr>
<td>How Should Patients Exposed to Ethylene Glycol Be Treated and Managed?</td>
<td>Describe treatment strategies for managing ethylene glycol poisoning cases</td>
</tr>
<tr>
<td>What Is Propylene Glycol?</td>
<td>Describe the uses of propylene glycol</td>
</tr>
<tr>
<td></td>
<td>Explain the potential risk of propylene glycol</td>
</tr>
<tr>
<td>What Instructions Should You Give to Patients Regarding Ethylene Glycol/Propylene Glycol Exposure?</td>
<td>• Describe self-care and clinical follow-up instructions for patients exposed to ethylene glycol or propylene glycol</td>
</tr>
</tbody>
</table>

| toxicity |  |
### Initial Check

<table>
<thead>
<tr>
<th><strong>Instructions</strong></th>
<th>This Initial Check will help you assess your current knowledge about ethylene glycol toxicity. To take the Initial Check, read the case below and then answer the questions that follow.</th>
</tr>
</thead>
</table>
| **Case Study, First Patient** | **Disorientation, Ataxia, and Abdominal Symptoms in Visitors to a Municipal Airport**  
A 67-year-old man arrives at the emergency department (ED) of a small community hospital where you are the family physician on call. The patient is experiencing  
- ataxia,  
- dizziness, and  
- vomiting.  
He is hyperventilating. On physical examination, the patient appears well nourished, but agitated and disoriented. He has no odor of ethanol on his breath.  
**Vital Signs**  
The patient’s vital signs are as follows:  
- Blood pressure (BP): 120/80 mm Hg  
- Temperature: 98.5°F  
- Pulse: 80 beats/minute  
- Respiration: 40 breaths/minute  
Neurologic examination is otherwise normal, with no focal findings, particularly no nystagmus. Abdominal examination is normal.  
**Additional Information**  
The patient’s friend brought him to the ED. The friend said that late the previous night the patient complained of dizziness and had begun to vomit. The patient was hyperventilating in the morning and continued to vomit. Both men are retired pilots who teach at the local airport’s ground school. The friend wonders whether the food at the airport cafeteria was responsible because two other people collapsed at the airport that morning. |
and were taken by ambulance to another hospital. Both the friend and the patient ate hot dogs and coleslaw from the cafeteria, but the friend states that he feels fine.

Results of Laboratory Tests

- Blood ethanol and routine urine drug screen are negative.
- Arterial blood gases (ABG) results: pH 7.10; PaCO₂ = 20 mm Hg; PaO₂ = 95 mm Hg; and bicarbonate = 8 mEq/L.
- Sodium: 145 mmol/L (normal 135–145 mmol/L).
- Potassium: 3.8 mmol/L (normal 3.1–5.3 mmol/L).
- Chloride: 105 mEq/L (normal 98–109 mEq/L).
- BUN: 20 mg/dL (normal 8–18 mg/dL).
- Creatinine: 1.0 mg/dl (normal 0.6–1.2 mg/dL).
- Glucose: 80 mg/dl (normal 65–110 mg/dL).
- Calculated anion gap: 32 (normal 12–16).

Note that results might vary from laboratory to laboratory and depend on the elevation above sea level (see Table 1).

<table>
<thead>
<tr>
<th>Table 1. Arterial blood gases – Ranges Considered Within Normal Limits at Sea Level and Breathing Room Air.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Oxygen content (O₂CT)</td>
</tr>
<tr>
<td>Oxygen saturation (O₂Sat)</td>
</tr>
<tr>
<td>---------------------------</td>
</tr>
</tbody>
</table>

**Case Study, Second Patient**

Fewer than 30 minutes later, a 4-year-old boy arrives at the ED. On examination, you find a sleepy but responsive child who shows no evidence of trauma or focal neurologic signs. Abdominal examinations are normal.

**Vital Signs**

The patient’s vital signs are as follows:
- BP: 94/76 mm Hg
- Rectal temperature: 98.5°F
- Respirations: 12 breaths/minute
- Pulse: 78 beats/minute

**Additional Information**

The parents tell you they were attending a local fliers’ club luncheon at the airport. When they noticed the child staggering and incoherent, they rushed him to the ED. On the way, he vomited in the car.

**Results of Laboratory Tests**

You order the same laboratory tests for the child that you ordered for the 67-year-old patient. The tests reveal that the child is
- hypoglycemic,
- has slight acidosis, and
- has an anion gap of 13.

**Additional Information**

You contact the local health department. They tell you they are investigating the earlier incidents at the airport. They have not identified the contaminant, but they suspect the airport’s water supply is contaminated.
| Initial Check Questions | 1. What would you include in the problem list for each patient? What is the differential diagnosis for an anion gap metabolic acidosis?  
2. What additional tests, if any, will you order for these patients?  
3. How will you initially treat these patients?  
4. What questions would health department investigators ask airport visitors and employees to establish the exposure source?  
5. The health department identifies the water contaminant as ethylene glycol. While repairing the water supply system, construction crews at the airport inadvertently connected the heating system water supply to the drinking water system. The concentration of ethylene glycol measured at the cafeteria’s water source was 9% (90,000 parts per million [ppm]). The U.S. Environmental Protection Agency (EPA) has an ethylene glycol drinking water quality guideline of 7 ppm (FSTRAC 1990). The lethal dose of 95% ethylene glycol is about 100 mL for an adult or 1.4 mL/kg.  
   Who in the case study might be at risk of adverse health effects? Explain.  
6. An airport employee comes to your office a week after the water contamination incident. One of his jobs is to de-ice aircraft. A major spill occurred on the previous day, drenching him with de-icing fluid. He knows that de-icing agents contain large amounts of ethylene glycol. Immediately after the spill, he showered and changed clothes. He is worried about possible adverse health effects, such as cancer. What will you tell him?  
   7. A pregnant airport worker consults you because she drank tea brewed with the contaminated water at the airport. Although she drank only a small amount of tea and had no ill effects, she is worried that even that small amount of contaminant will adversely affect her fetus. How will you counsel her? |
|---|---|
8. You later learn that during dinner at the cafeteria, the 67-year-old man drank several cups of coffee, while his friend, who did not become ill, drank only canned soda. The serum ethylene glycol level for the 67-year-old patient is 55 mg/dL; the anion gap is 35. How will you treat the 67-year-old patient?

9. The child’s ethanol level is 85 mg/dL. You repeat the ethanol test, and again the result is high. The parents are incredulous. They state the luncheon did include wine and cocktails, but they did not supervise the child closely. Potential ethylene glycol exposure sources for the child were not immediately identifiable. How will you treat the child?

**Initial Check Answers**

1. The man’s medical problems include the following:
   - Ataxia
   - Vomiting
   - Agitation
   - Disorientation
   - Hyperventilation
   - Elevated anion-gap metabolic acidosis

   The child’s medical problems include the following:
   - Somnolence
   - Ataxia
   - Mental status changes
   - Vomiting
   - Hypoglycemia
   - Low body temperature
   - Slight anion-gap metabolic acidosis

   Differential diagnoses include toxic alcohol ingestion and diabetic or starvation ketoacidosis.

   (Table 3 shows common toxic agents associated with an elevated anion gap.)
2. Additional testing of these patients should include the following:

- Urinalysis
- Complete blood count
- Serum osmolality measured by the freezing-point–depression technique
- Ethylene glycol and methanol levels
- Ammonia, acetaminophen, and aspirin levels
- Liver function

Find more information for this answer in the “Clinical Assessment – Laboratory Tests” section.

3. Because the critical ingestion occurred several hours ago, emesis or gastric lavage will be of little value, and activated charcoal will be ineffective. However, it is important to act promptly to correct the metabolic acidosis and to prevent further conversion of the remaining ethylene glycol into its toxic metabolites.

Intravenous administration of the antidote, fomepizole, will inhibit further ethylene glycol metabolism. In the absence of both renal insufficiency and significant metabolic acidosis, fomepizole may be used without hemodialysis. Start hemodialysis if severe metabolic acidosis or renal failure develops.

Find more information for this answer in the “How should patients exposed to ethylene glycol be treated and managed?” section.

4. The most common sources of epidemic poisonings include

- contaminated food,
- beverages, and
- water supplies.

Incident investigators would ask about types of food and drink available at the airport. They would take a detailed history of food and beverage intake
from the patients and all others at the airport. They would attempt to find a common factor that would include those who were ill and exclude those who did not become ill. Investigators can usually identify the exposure source or restrict the exposure source possibilities by gathering and statistically analyzing data from a large group of people.

Find more information for this answer in the “Where is ethylene glycol found?” section.

5. The lethal dose of antifreeze (95% ethylene glycol) is about 100 mL or 1.4 mL/kg, although amounts in the reported cases vary widely. A cup (240 mL) of the contaminated water would contain about 22 mL of ethylene glycol. This dose could cause significant toxicity. Even mild symptoms of ethylene glycol poisoning would be a concern for air traffic controllers and other airport personnel responsible for judgments affecting many lives. Healthcare providers should examine every employee and visitor who consumed beverages or food prepared with water at the airport.

Find more information for this answer in the “Where is ethylene glycol found?” section.

6. Absorption of ethylene glycol is minimal through intact skin and is not likely to lead to toxic effects. Because the patient showered and changed clothes immediately, it is unlikely he will experience toxic effects from the spill. In the case of chronic exposure during the de-icing process, few particles from a spraying device are likely to be inhaled, so inhalation of ethylene glycol would be minimal. Contact during the de-icing process would not contribute substantially to toxicity, especially if the exposed person wore protective clothing and respiratory protection. No studies were located regarding carcinogenicity in humans after exposure to ethylene glycol.
7. You can inform the pregnant patient that experimental animal studies indicate that ethylene glycol at high, prolonged levels can cause developmental effects. However, no human studies specifically assess the effects of ethylene glycol on fetal development.

Find more information for this answer in the “What are the toxicological effects of ethylene glycol poisoning?” section.

8. The initial treatment is described in answer 3. Traditionally, an ethylene glycol level of 50 mg/dL was an indication for hemodialysis. However, some patients with normal renal function and no evidence of metabolic acidosis have been treated effectively with fomepizole, despite having ethylene glycol levels of 50 mg/dL. In the absence of both renal insufficiency and significant metabolic acidosis, fomepizole may be used without hemodialysis. Hemodialysis should be started if metabolic acidosis develops.

Find more information for this answer in the “How should patients exposed to ethylene glycol be treated and managed?” section.

9. The child could be intoxicated with ethanol alone or with ethanol and ethylene glycol. If intoxication is from ethanol only, carefully monitor blood glucose and ethanol until the intoxication resolves. If laboratory results indicate that ingestion of ethylene glycol occurred, the patient can be treated with fomepizole. The limited data available suggest that fomepizole, at the same dosage used for adults, is effective and well tolerated in pediatric patients. For many pediatric patients treated with fomepizole for ethylene glycol poisoning, hemodialysis might not be
needed, despite high ethylene glycol concentrations and the presence of metabolic acidosis.

Find more information for this answer in the “How should patients exposed to ethylene glycol be treated and managed?” section.

---

### What Is Ethylene Glycol?

<table>
<thead>
<tr>
<th><strong>Learning Objectives</strong></th>
<th>After completing this section, you will be able to describe the properties of ethylene glycol.</th>
</tr>
</thead>
</table>

Page 19 of 124
**Definition**

Ethylene glycol is a liquid that is

- clear,
- colorless,
- odorless, and
- sweet tasting.

Ethylene glycol has low vapor pressures at room temperature and, therefore, low potential for significant inhalation exposure.

Its chemical structure is HOCH₂CH₂OH.

```
H   C   C   OH
O   H   H
H   H
```

**Synonyms**

Common synonyms for ethylene glycol include

- ethylene alcohol,
- glycol alcohol,
- glycol,
- 1,2-dihydroxyethane, and
- 1,2-ethanediol.

**Properties**

Ethylene glycol

- dissolves in water and alcohol,
- can hold large amounts of heat before boiling,
- lowers the freezing point of water, and
- absorbs twice its weight in water.
### Uses

Ethylene glycol is widely used as antifreeze (concentration range: 80%–99%) or de-icing solutions (concentration range: 3%–40%) for cars, boats, and aircraft. It is also used in the chemical synthesis of plastics, films, and solvents. It can be found in many consumer products, including solvents, paints, and coolants (concentration range: 20%–95%) (Caravati et al. 2005).

### Toxicity

Ethylene glycol poisoning is a relatively common occurrence worldwide. Thousands of cases of poisoning and some fatal cases occur annually in the United States alone (AAPCC 2016).

Systemic ethylene glycol toxicity can occur following ingestion. The toxic metabolic by-products of ethylene glycol metabolism cause a buildup of acids in the blood (metabolic acidosis). These toxic substances first affect the central nervous system, then the cardiopulmonary system, and finally can cause renal failure. Untreated ethylene glycol poisoning can be fatal (NIOSH 2014). The lethal oral dose in humans is approximately 1.4 mL/kg of pure ethylene glycol (Brent 2001).

### Key Points

- Ethylene glycol is widely used in antifreeze and in de-icing solutions for cars, boats, and aircraft.
- Untreated ethylene glycol poisoning can be fatal.

### Progress Check

1. Which of the following statements is NOT true?

   A. Ethylene glycol is a colorless, odorless, and sweet-tasting liquid.
   B. Ethylene glycol can lower the freezing point of water.
   C. Ethylene glycol can hold large amounts of heat before boiling.
   D. Ethylene glycol poisoning is rare.
<table>
<thead>
<tr>
<th>Answers</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. The false statement is D. Ethylene glycol poisoning is, in fact, a relatively common occurrence worldwide. More than 5,000 cases of poisoning occur in the United States each year. Untreated ethylene glycol poisoning can be fatal; such deaths have occurred annually in the United States. Additionally, ethylene glycol is a colorless, odorless, and sweet-tasting liquid that can lower the freezing point of water and hold large amounts of heat before boiling.</td>
</tr>
</tbody>
</table>

Feedback for A. (Web only): The false statement is D. In fact, ethylene glycol poisoning is a relatively common occurrence worldwide. Additionally, ethylene glycol is a colorless, odorless, and sweet-tasting liquid. It can lower the freezing point of water and hold large amounts of heat before boiling. |

Feedback for B. (Web only): The false statement is D. In fact, ethylene glycol poisoning is a relatively common occurrence worldwide. Ethylene glycol also can lower the freezing point of water. It is a colorless, odorless, and sweet-tasting liquid that holds large amounts of heat before boiling. |

Feedback for C. (Web only): The false statement is D. In fact, ethylene glycol poisoning is a relatively common occurrence worldwide. Ethylene glycol also can hold a large amount of heat before boiling. It can lower the freezing point of water and is a colorless, odorless, and sweet-tasting liquid. |

Feedback for D. (Web only): Correct. The false statement is D. In fact, ethylene glycol poisoning is a relatively common occurrence worldwide. More than 5,000 cases of poisoning occur in the United States each year. Untreated ethylene glycol poisoning can be fatal; such deaths have occurred annually in the United States. Additionally, ethylene glycol is a colorless, odorless, and sweet-tasting liquid. It can lower the freezing point of water and hold large amounts of heat before boiling. |
To review relevant content, see “Definition”, “Properties”, and “Toxicity” in this section.

Where Is Ethylene Glycol Found?

<table>
<thead>
<tr>
<th>Learning Objective</th>
<th>After completing this section, you will be able to identify sources of ethylene glycol exposure.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduction</td>
<td>The most common source of ethylene glycol exposure is antifreeze. Antifreeze, which is readily available at hardware and automotive stores, can contain up to 95% ethylene glycol. The primary sources of ethylene glycol in the environment are disposal of used antifreeze and use of de-icing solutions at airports (ATSDR 2010; EPA 2000).</td>
</tr>
<tr>
<td>Environmental Sources</td>
<td>The primary sources of ethylene glycol in the environment are from disposal of used antifreeze and use of de-icing solutions at airports.</td>
</tr>
<tr>
<td>Air</td>
<td>Ethylene glycol does not persist in large amounts in ambient air. This is because breakdown is rapid (half-life in air is 8–84 hours).</td>
</tr>
<tr>
<td><strong>Water</strong></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
<tr>
<td>Ethylene glycol is miscible with water. Its half-life ranges from 2 to 12 days in surface water and 4 to 24 days in groundwater. Bioconcentration and bioaccumulation are insignificant because ethylene glycol is not fat-soluble and biodegrades rapidly [Howard 1991].</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Soil</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethylene glycol will leach through soil to groundwater. It biodegrades rapidly in soil (ATSDR 2010).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Occupational Sources</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Workers in industries producing or using products containing ethylene glycol might be exposed to ethylene glycol.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Sources from consumer products</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>A number of household products contain ethylene glycol as an ingredient [(NLM 2016)]. Those containing high concentrations of ethylene glycol include antifreeze products.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Key Points</strong></th>
</tr>
</thead>
</table>
| • The primary sources of ethylene glycol in the environment are disposal of used antifreeze and use of de-icing solutions at airports.  
• Most antifreeze products contain high concentrations of ethylene glycol. |

<table>
<thead>
<tr>
<th><strong>Progress Check</strong></th>
</tr>
</thead>
</table>
| 2. The most common source of ethylene glycol exposure that leads to poisoning in the general U.S. population is which of the following?  
   A. Polyester fibers  
   B. Antifreeze  
   C. Cosmetics  
   D. Resin products |

<table>
<thead>
<tr>
<th><strong>Answer</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>2. The best choice is B. Ethylene glycol is a significant ingredient of automotive fluids such as antifreeze, coolants, and hydraulic fluids. Antifreeze, which typically consists of 95% ethylene glycol, accounts</td>
</tr>
</tbody>
</table>
for about 40% of the ethylene glycol produced. It is sold in many hardware and automotive stores and therefore easily accessible to the public.

Feedback for A. (Web only): The best choice B. The industrial uses of ethylene glycol include production of polyester fibers, films, resin products, cosmetics, and fat extractants. Antifreeze, however, which typically consists of 95% ethylene glycol and accounts for about 40% of ethylene glycol produced, is the most common source of ethylene glycol exposure in the general population.

Feedback for B. (Web only): Correct. The best choice is B. Ethylene glycol is a significant ingredient of automotive fluids such as antifreeze, coolants, and hydraulic fluids. Antifreeze, which typically consists of 95% ethylene glycol, accounts for about 40% of the ethylene glycol produced. It is sold in many hardware and automotive stores and therefore easily accessible to the public.

Feedback for C. (Web only): The best choice is B. The industrial uses of ethylene glycol include production of polyester fibers, films, resin products, cosmetics, and fat extractants. Antifreeze, however, which typically consists of 95% ethylene glycol and accounts for about 40% of ethylene glycol produced, is the most common source of ethylene glycol exposure in the general population.

Feedback for D. (Web only): The best choice is B. The industrial uses of ethylene glycol include production of polyester fibers, films, resin products, cosmetics, and fat extractants. Antifreeze, however, which typically consists of 95% ethylene glycol and accounts for about 40% of ethylene glycol produced, is the most common source of ethylene glycol exposure in the general population.

What Are Routes of Exposure to Ethylene Glycol?

<table>
<thead>
<tr>
<th>Learning Objective</th>
<th>After completing this section, you will be able to identify the most common route of exposure to ethylene glycol that results in toxicity in the general U.S. population.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduction</td>
<td>Accidental or intentional ingestion of antifreeze is the most common route of exposure leading to ethylene glycol toxicity, resulting in thousands of poisonings reported each year in the United States (AAPCC 2016; ATSDR 2010). Ethylene glycol is not expected to be found in the environment away from areas where it is released. Outside of those areas, the general public has little risk for exposure through air, drinking water, or skin contact with water or soil.</td>
</tr>
<tr>
<td>Dermal</td>
<td>Skin contact is the most likely route of occupational exposure. However, dermal absorption is limited and exposure by this route is generally not likely to lead to toxic effects. Dermal exposure to ethylene glycol may occur while handling • automotive antifreezes, • coolants, and • brake fluids. Such exposures are not likely to cause adverse health effects.</td>
</tr>
<tr>
<td>Inhalation</td>
<td>Ethylene glycol’s low vapor pressure precludes substantial inhalation exposure at ambient temperatures in the environment (Howard PH 1991). Upper respiratory tract irritation is possible when the liquid is heated, agitated, or sprayed.</td>
</tr>
</tbody>
</table>
| **Ingestion** | Accidental or intentional ingestion of antifreeze is the most common route of exposure leading to ethylene glycol toxicity, resulting in thousands of poisonings reported each year in the United States (AAPCC 2016; ATSDR 2010)].

In the general U.S. population, ethylene glycol exposure occurs most commonly through antifreeze ingestion. Annual reports of the American Association of Poison Control Centers (AAPCC) have reported

- 6,600 ethylene glycol exposures and 16 deaths in 2013,
- 6,809 ethylene glycol exposures and 26 deaths in 2014, and
- 6,895 ethylene glycol exposures and 22 deaths in 2015.

| **Key Points** | - Accidental or intentional ingestion of antifreeze is the most common route of exposure leading to ethylene glycol toxicity, resulting in thousands of poisonings reported each year in the United States.
- Inhalation of ambient air, ingestion of drinking water, or skin contact with water or soil are not expected to be significant routes of exposure for the general U.S. population.

| **Progress Check** | 3. Which of the following is the most common route of exposure leading to ethylene glycol toxicity in the general U.S. population?

A. Inhalation.
B. Ingestion.
C. Dermal contact.
D. All of the above are equally common routes of exposure leading to ethylene glycol toxicity in the general U.S. population.
### Answer

3. The best choice is B. In the general U.S. population, ethylene glycol toxicity occurs most commonly through accidental or intentional antifreeze ingestion. Although the most likely route of occupational exposure is skin contact, such dermal exposure rarely leads to toxic effects.

Feedback for A. (Web only): The best choice is B. The most common route of exposure leading to ethylene glycol toxicity in the general U.S. population is by ingestion. Because of its low vapor pressure at room temperature, the potential for ethylene glycol toxicity is limited for inhalation exposures. However, people can inhale ethylene glycol vapor and mist, particularly when the chemical is heated, agitated, or sprayed.

Feedback for B. (Web only): Correct. In the general U.S. population, ethylene glycol toxicity occurs most commonly through accidental or intentional antifreeze ingestion. Although the most likely route of occupational exposure is skin contact, such dermal exposure rarely leads to toxic effects.

Feedback for C. (Web only): The best choice is B. The most common route of exposure leading to ethylene glycol toxicity in the general U.S. population is by ingestion. Although skin contact is the most likely occupational exposure route, such dermal exposure rarely leads to toxic effects. Under normal conditions, skin contact while handling automotive antifreezes, coolants, and brake fluids is not likely to cause adverse health effects.

Feedback for D. (Web only): The best choice is B. In the general U.S. population, ethylene glycol toxicity occurs most commonly through accidental or intentional antifreeze ingestion. Although skin contact is the most likely route of occupational exposure, such dermal exposure rarely leads to toxic effects. Inhalation exposure can occur, but is not the most common route leading to ethylene glycol toxicity in the general U.S. population.
To review relevant content, see “Ingestion” in this section.
## Who is at Risk of Exposure to Ethylene Glycol?

<table>
<thead>
<tr>
<th>Learning Objectives</th>
<th>After completing this section, you will be able to identify who is at risk of exposure to ethylene glycol.</th>
</tr>
</thead>
</table>
| **Introduction**    | For the general population, the primary risk of exposure to ethylene glycol is through contact with automobile antifreezes and coolants.  
People potentially at greater risk for ethylene glycol exposure include those who live near  
- airports where large amounts of ethylene glycol are used for aircraft de-icing or  
- hazardous waste sites contaminated with ethylene glycol.  
Workers in industries producing or using products that contain ethylene glycol are at greatest risk for exposure. |
| **General U.S. Population** | In the general U.S. population, exposure leading to ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze. The 2015 annual report of the American Association of Poison Control Centers documented 6,895 ethylene glycol exposures and 22 deaths.  
The general U.S. population also can be exposed to ethylene glycol by skin contact while handling automotive antifreezes, coolants, and brake fluids. However, such exposure is generally not likely to cause adverse health effects. |
| Special Populations – Environmental Exposures | Persons living near airports where large amounts of ethylene glycol are used for aircraft de-icing or persons who live near hazardous waste sites contaminated with ethylene glycol are potentially at greater risk for ethylene glycol exposure, particularly if they consume contaminated groundwater. Large amounts of ethylene glycol are sprayed onto airplane wings as an aerosol or mist to prevent ice buildup. Used in this manner, ethylene glycol might contaminate groundwater near airports through runoff. The spray also might expose workers to air levels ranging from .05- 22 milligrams per cubic meter (mg/m³) [(ATSDR 2010).

Ethylene glycol rapidly degrades in air, water, and soil. Available monitoring data indicate that it is only found near areas of release. Ethylene glycol is not expected to be found in the environment away from areas where it is released. Because of that, the general U.S. population is not expected to be exposed to significant environmental background levels of this substance (ATSDR 2010). |
| Workers - Occupational Exposure | Products containing high concentrations of ethylene glycol include antifreeze, coolants, de-icing fluids, brake fluids, solvents, and latex paints. Workers in industries producing or using those products potentially are at high risk for exposure.

Although skin contact is the main route of occupational exposure, vapors or mists can be inhaled when the chemical is heated, agitated, or sprayed. |
### Key Points

- In the general U.S. population, ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze.

- People potentially at increased risk for ethylene glycol exposure include those who live near
  - hazardous waste sites contaminated with ethylene glycol,
  - industrial facilities where ethylene glycol is produced or used, or
  - areas where ethylene glycol-based de-icing formulations are used.

- Workers in industries producing or using products that contain ethylene glycol are at potentially increased risk of exposure.

### Progress Check

4. Which of the following statements about risk of exposure is NOT true?

A. Ethylene glycol might contaminate groundwater near airports through runoff and might expose workers.

B. People living near airports where large amounts of ethylene glycol are used for aircraft de-icing potentially are at greater risk for ethylene glycol exposure.

C. In the general population, ethylene glycol toxicity occurs most commonly through skin contact with antifreeze.

D. Because ethylene glycol is mostly limited to areas where it is released, the general U.S. population is not expected to be exposed to significant environmental background levels of this substance.
4. The false statement is C. In the general population, ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze. The general U.S. population can be exposed to ethylene glycol by skin contact while handling automotive antifreezes, coolants, and brake fluids. However, such exposure is less likely to cause adverse health effects. Ethylene glycol could contaminate groundwater near airports through runoff and might expose workers. People living near airports where large amounts of ethylene glycol are used for aircraft de-icing potentially are at greater risk for ethylene glycol exposure. Because ethylene glycol is not expected to be found in the environment away from areas where it is released, the general U.S. population is not expected to be exposed to significant environmental background levels of this substance.

Feedback for A. (Web only): The false statement is C. In the general population, ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze. The general U.S. population can be exposed to ethylene glycol by skin contact while handling automotive antifreezes, coolants, and brake fluids. However, such exposure is less likely to cause adverse health effects. The other statements are true.

- Ethylene glycol might contaminate groundwater near airports through runoff and might expose workers.
- People living near airports where large amounts of ethylene glycol are used for aircraft de-icing potentially are at greater risk for ethylene glycol exposure.
- Because ethylene glycol is not expected to be found in the environment away from areas where it is released, the general U.S. population is not expected to be exposed to significant environmental background levels of this substance.
Feedback for B. (Web only): The false statement is C. In the general population, ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze. The general U.S. population can be exposed to ethylene glycol by skin contact while handling automotive antifreezes, coolants, and brake fluids. However, such exposure is less likely to cause adverse health effects. The other statements are true.

- People living near airports where large amounts of ethylene glycol are used for aircraft de-icing potentially are at greater risk for ethylene glycol exposure.
- Ethylene glycol might contaminate groundwater near airports through runoff and might expose workers.
- Because ethylene glycol is not expected to be found in the environment away from areas where it is released, the general U.S. population is not expected to be exposed to significant environmental background levels of this substance.

Feedback for C. (Web only): Correct. The false statement is C. In the general population, ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze. The general U.S. population can be exposed to ethylene glycol by skin contact while handling automotive antifreezes, coolants, and brake fluids. However, such exposure is less likely to cause adverse health effects. The other statements are true.

- Ethylene glycol might contaminate groundwater near airports through runoff and might expose workers.
- People living near airports where large amounts of ethylene glycol are used for aircraft de-icing potentially are at greater risk for ethylene glycol exposure.
- Because ethylene glycol is not expected to be found in the environment away from areas where it is released, the general U.S. population is not expected to be exposed to
significant environmental background levels of this substance.

Feedback for D. (Web only): The false statement is C. In the general U.S. population, ethylene glycol toxicity occurs most commonly through accidental or intentional ingestion of antifreeze. The general U.S. population can be exposed to ethylene glycol by skin contact while handling automotive antifreezes, coolants, and brake fluids. However, such exposure is less likely to cause adverse health effects. The other statements are true.

- Because ethylene glycol is not expected to be found in the environment away from areas where it is released, the general U.S. population is not expected to be exposed to significant environmental background levels of this substance.
- Ethylene glycol might contaminate groundwater near airports through runoff and might expose workers.
- People living near airports where large amounts of ethylene glycol are used for aircraft de-icing potentially are at greater risk for ethylene glycol exposure.

# What Are U.S. Regulations and Guidelines for Ethylene Glycol Exposure?

<table>
<thead>
<tr>
<th>Learning Objectives</th>
<th>After completing this section, you will be able to describe current U.S. regulations and guidelines for ethylene glycol exposure.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduction</strong></td>
<td>The U.S. government has developed ethylene glycol regulations and guidelines intended to protect the public and workers from potential adverse health effects should exposure occur.</td>
</tr>
</tbody>
</table>
| **Workplace Standards** | The Occupational Safety and Health Administration (OSHA) has not established a permissible exposure limit (PEL).  

The National Institute for Occupational Safety and Health (NIOSH) has provided a recommended ethylene glycol exposure limit (REL) of 50 ppm (ceiling limit) (NIOSH 2005).  

The American Conference of Governmental Industrial Hygienists (ACGIH) has established threshold limit values (TLVs) for workplace exposure [(ACGIH 2017)]. |
| **Environmental Standards** | **Air**  
The Environmental Protection Agency (EPA) has designated ethylene glycol as a hazardous air pollutant under the Clean Air Act (EPA 2007).  

**Water**  
EPA recommends that children not be exposed to more than 20 mg/L (20 ppm) ethylene glycol in drinking water for 1 day, or 6 mg/L (6 ppm) per day over 10 days.  

EPA also recommends that adults not be exposed to more than a daily total of 7 mg/L (7 ppm) for a lifetime [FSTRAC 1990]. |
### Food

The Food and Drug Administration (FDA) has approved ethylene glycol as an indirect food additive, for use only as a component of packaging adhesives.

The U.S. Department of Health and Human Services (HHS), the International Agency for Research on Cancer (IARC), and EPA have not classified ethylene glycol as a human carcinogen.

### Key Points

- NIOSH and ACGIH have established limits for exposure to ethylene glycol in the workplace.
- EPA has established limits for exposure to ethylene glycol in drinking water for children and adults.
- Ethylene glycol is not classified as a human carcinogen.

### Progress Check

5. Which of the following statements is **FALSE** regarding U.S. government guidelines for ethylene glycol exposure?

   A. EPA has established exposure limits of ethylene glycol in drinking water for children and adults.
   B. ACGIH has established threshold limit values for workplace exposure.
   C. FDA has approved ethylene glycol as an indirect food additive.
   D. Ethylene glycol is classified as a human carcinogen.
| Answers | 5. The false statement is D. Ethylene glycol is not classified as a human carcinogen. The other statements are true.  
  
  - EPA has established limits to ethylene glycol exposure in drinking water for children and adults.  
  - ACGIH has established threshold limit values for workplace exposure.  
  - FDA has approved ethylene glycol as an indirect food additive.  
  
  Feedback for A. (Web only): The false statement is D. Ethylene glycol is not classified as a human carcinogen. The other statements are true.  
  
  - EPA has established limits to ethylene glycol exposure in drinking water for children and adults.  
  - ACGIH has established threshold limit values for workplace exposure.  
  - FDA has approved ethylene glycol as an indirect food additive.  
  
  Feedback for B. (Web only): The false statement is D. Ethylene glycol is not classified as a human carcinogen. The other statements are true.  
  
  - ACGIH has established threshold limit values for workplace exposure.  
  - EPA has established limits to ethylene glycol exposure in drinking water for children and adults.  
  - FDA has approved ethylene glycol as an indirect food additive.  
  
  Feedback for C. (Web only): The false statement is D. Ethylene glycol is not classified as a human carcinogen. The other statements are true.  
  
  - FDA has approved ethylene glycol as an indirect food additive.  
  - EPA has established limits to ethylene glycol exposure in drinking water for children and adults. |
ACGIH has established threshold limit values for workplace exposure.

Feedback for D. (Web only): Correct. Ethylene glycol is not classified as a human carcinogen. The other statements are true,

- EPA has established limits to ethylene glycol exposure in drinking water for children and adults.
- ACGIH has established threshold limit values for workplace exposure.
- FDA has approved ethylene glycol as an indirect food additive.

To review relevant content, see “Environmental Standards” in this section.

**What Is the Biological Fate of Ethylene Glycol?**

<table>
<thead>
<tr>
<th><strong>Learning Objectives</strong></th>
<th>After completing this section, you will be able to explain the major pathway of ethylene glycol metabolism in the body.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduction</strong></td>
<td>Ethylene glycol is rapidly absorbed from the gastrointestinal tract and slowly absorbed through the skin or lungs. It is distributed throughout total body water. Most of an absorbed dose of ethylene glycol is metabolized by the liver and a small portion is excreted unchanged in the urine.</td>
</tr>
</tbody>
</table>
| **Absorption and Distribution** | Ethylene glycol is rapidly absorbed from the gastrointestinal tract and slowly absorbed through the skin or lungs. Studies involving animals fed single doses of ethylene glycol by gavage show that absorption is rapid and nearly complete. Peak plasma concentrations occurred in 1–4 hours, increasing linearly with dose among various species (i.e., rats, mice, monkeys). (International Programme on Chemical Safety 2002).

Because it is highly water-soluble, ethylene glycol is distributed throughout total body water. The normal serum half-life of ethylene glycol is estimated at about 2.5 hours in children and 3–8 hours in untreated adults (Eder et al. 1998). |
| **Metabolic Pathway** | The parent compound ethylene glycol has relatively low toxicity other than its inebriating effects. The liver metabolizes ethylene glycol by successive oxidations to a variety of compounds that include

- glycoaldehyde,
- glycolic acid,
- glyoxylic acid, and
- oxalic acid.

These compounds are more toxic than ethylene glycol itself (Figure 1).

The rate-limiting step in this metabolic process is the conversion of ethylene glycol to glycoaldehyde, a process catalyzed by alcohol dehydrogenase (ADH).

Several factors might influence susceptibility to ethylene glycol-induced toxicity, including the following:

- Individual differences in ADH activity
- Nutritional deficiencies, notably lack of thiamine or pyridoxine (two vitamins that mediate the metabolic detoxification of ethylene glycol)

Concomitant ethanol exposure can decrease or prevent toxicity by preferentially competing for ADH, thereby inhibiting transformation of ethylene glycol to glycoaldehyde. |
Figure 1. Metabolism of ethylene glycol. Adapted from (Hall AH 1992).
| Elimination | If the patient is free of ethanol exposure, the liver metabolizes approximately 80% of an absorbed dose of ethylene glycol [Brent 2001].

A small fraction of ethylene glycol (less than 20% after low-dose ingestion) passes unchanged in the urine.

The breakdown of ethylene glycol metabolites can generate CO₂, which is eliminated through the lungs (ATSDR 2010). |
|---|---|
| Key Points | • Ethylene glycol is rapidly absorbed from the gastrointestinal tract and slowly absorbed through the skin or lungs.
• Ethylene glycol is metabolized in the liver to a variety of more toxic compounds.
• In untreated adults, approximately 20% of a dose of ethylene glycol is excreted unchanged by the kidneys.
• The half-life of ethylene glycol in untreated adult patients is 3–8 hours. |
| Progress Check | After being absorbed in the body, what happens to most of the ethylene glycol?
A. It is metabolized in the kidney.
B. It is eliminated unchanged by the kidneys.
C. It is metabolized in the liver.
D. It is eliminated unchanged by the lungs. |
| Answer | 6. The correct answer is C. About 80% of an absorbed dose of ethylene glycol is metabolized in the liver.

Feedback for A. (Web only): The correct answer is C. About 80% of an absorbed dose of ethylene glycol is metabolized in the liver. Only a small portion (less than 20%) of absorbed ethylene glycol is eliminated unchanged by the kidney.

Feedback for B. (Web only): The correct answer is C. About 80% of an absorbed dose of ethylene
glycol is metabolized in the liver. Only a small portion (less than 20%) of absorbed ethylene glycol is eliminated unchanged by the kidney.

Feedback for C. (Web only): Correct. About 80% of an absorbed dose of ethylene glycol is metabolized in the liver.

Feedback for D. (Web only): The correct answer is C. About 80% of an absorbed dose of ethylene glycol is metabolized in the liver. The breakdown of metabolites of ethylene glycol can generate CO$_2$, which is one of the elimination pathways of ethylene glycol through the lungs.

To review relevant content, see “Metabolic Pathway” and “Elimination” in this section.

What Are the Toxicological Effects of Ethylene Glycol Poisoning?

<table>
<thead>
<tr>
<th>Learning Objectives</th>
<th>After completing this section, you will be able to describe the toxicological effects of ethylene glycol poisoning.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduction</td>
<td>Ethylene glycol’s toxicity mainly results from the accumulation of its toxic metabolites.</td>
</tr>
<tr>
<td></td>
<td>Ethylene glycol is a central nervous system (CNS) depressant that produces acute effects similar to those of ethanol. These CNS effects predominate during the first hours after exposure.</td>
</tr>
<tr>
<td></td>
<td>If undetected or untreated, ethylene glycol ingestion can cause serious or fatal toxicity. This section describes the systemic effects associated with significant ethylene glycol exposure.</td>
</tr>
</tbody>
</table>
| **Mechanism of Toxicity** | The main toxicity of ethylene glycol results from hepatic metabolism of ethylene glycol to  
| | • glycoaldehyde,  
| | • glycolate,  
| | • glyoxylate, and  
| | • oxalate.  
| | These metabolites inhibit  
| | • oxidative phosphorylation and cellular respiration,  
| | • glucose and serotonin metabolism,  
| | • protein synthesis,  
| | • DNA replication, and  
| | • ribosomal RNA formation.  
| | The effects include CNS depression and cardiopulmonary and renal failure (Bove 1966; Jacobsen and McMartin 1986).  
| | The accumulation of organic acid metabolites, especially glycolic acid, results in an elevated anion gap metabolic acidosis.  

| **Stages of Intoxication** | • A three-stage theory of ethylene glycol poisoning was introduced in the 1950s (Berman et al. 1957; Kahn and Brotchner 1950). These stages are theoretical descriptions of ethylene glycol poisoning, but the onset and progression of the clinical course is frequently not consistent or predictable. One stage might predominate, whereas another stage might be absent (Jammalamadaka and Raissi 2010).  
| | • The three stages include the following:  
| | o Stage 1 (the neurological stage) occurs within 30 minutes to 12 hours after ingestion.  
| | o Stage 2 (the cardiopulmonary stage) occurs between 12 and 24 hours after ingestion.  
| | o Stage 3 (the renal stage) occurs between 24 and 72 hours after ingestion.  

Neurologic Effects

The initial phase of ethylene glycol poisoning in humans is characterized by inebriation caused by unmetabolized ethylene glycol. The following effects are common in acute poisoning cases (Buell et al. 1998; Hess et al. 2004; Parry and Wallach 1974):

- Ataxia
- Slurred speech
- Drowsiness
- Irritation
- Restlessness
- Disorientation

Possible consequences of neurologic effects in severe poisonings (Froberg et al. 2006; Hantson et al. 2002; Walder and Tyler 1994) include the following:

- Myoclonic jerks
- Convulsions
- Coma
- Death

Cerebral edema and deposition of calcium oxalate crystals in the walls of small blood vessels in the brain contribute to this CNS toxicity (Bey et al. 2002; Froberg et al. 2006; Jobard et al. 1996; Tobe et al. 2002). Some studies have documented brain dysfunction with corresponding cranial computed tomography (CT) findings after ethylene glycol ingestion, such as low-density areas in the basal ganglia, thalami, midbrain, and upper pons. The neurologic findings reflect dysfunction of all the areas of hypodensity on the cranial CT scan. In one study, magnetic resonance imaging of the brain obtained 24 days after ingestion revealed
bilateral putamen necrosis (Chung and Tuso 1989; Morgan et al. 2000; Zeiss et al. 1989).

According to some investigators, effects on cranial nerves appear late (generally 5–20 days after ingestion) and constitute a fourth, late cerebral phase in ethylene glycol intoxication (Chung and Tuso 1989; Gardner et al. 2004; Lewis et al. 1997). The following cranial nerve effects have been reported after acute exposure:

- Facial palsy
- Hearing loss
- Dysphagia
- Ophthalmoplegia
- Visual disturbances

Such adverse effects are uncommon, but delayed treatment might contribute to their development (Broadley et al. 1997; Lewis et al. 1997; Momont and Dahlberg 1989; Tobe et al. 2002).

<table>
<thead>
<tr>
<th>Respiratory Effects</th>
<th>Inhaled ethylene glycol can irritate the respiratory tract (Wills et al. 1974).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- Throat and upper respiratory irritation were the most common complaints after prolonged experimental exposures in humans (4 weeks at concentrations of 1–25 parts per million [ppm]).</td>
</tr>
<tr>
<td></td>
<td>- Exposure to 60 ppm aerosolized ethylene glycol caused noticeable respiratory irritation.</td>
</tr>
<tr>
<td></td>
<td>- Exposure to 80 ppm aerosolized ethylene glycol was “intolerable” because respiratory discomfort developed rapidly.</td>
</tr>
</tbody>
</table>

Pulmonary effects typically occur 12–72 hours after ethylene glycol ingestion. Pulmonary edema, adult respiratory distress syndrome (ARDS), and death have occurred in persons exposed to ethylene glycol (Gordon and Hunter 1982; Haupt et al. 1988; Piagnerelli et al. 1999).
The following respiratory effects often occur 12 hours or more after exposure in victims of severe ethylene glycol poisoning:

- Tachypnea
- Hyperventilation
- Kussmaul respirations

Such effects most often reflect physiological compensation for severe metabolic acidosis rather than primary lung disease (Friedman et al. 1962; Godolphin et al. 1980; Parry and Wallach 1974). Autopsies (Vale 1979) of ethylene glycol victims revealed the following:

- Pulmonary edema with diffuse hemorrhagic exudates
- Bronchopneumonia (probably caused by aspiration)
- Deposits of calcium oxalate crystals in lung parenchyma

**Cardiovascular Effects**

The following severe cardiovascular effects have been reported in persons 12-24 hours (stage 2) after ingesting ethylene glycol (Friedman et al. 1962; Gordon and Hunter 1982; Parry and Wallach 1974; Vale 1979):

- Hypertension or hypotension
- Dysrhythmias (from electrolyte abnormalities)
- Congestive heart failure with cardiogenic pulmonary edema
- Circulatory collapse
- Cardiac arrest
- Death
| **Metabolic Effects** | Ethylene glycol exposure is characterized by an elevated osmolal gap and metabolic acidosis with an elevated anion gap.  
- Onset occurs within 24 hours after ingestion.  
- Acidosis is caused primarily by the accumulation of glycolic and glyoxylic acids. Oxalic acid and lactic acid also contribute.  

Ethylene glycol is a small, osmotically active molecule that  
- increases plasma osmolality, and  
- can cause a large osmolal gap.  

Tetany, including muscle twitches, cramps, and contractions, can sometimes result from hypocalcemia, which results from calcium precipitation by the oxalate formed during ethylene glycol metabolism (Parry and Wallach 1974). |
|---|---|
| **Renal Effects** | Adverse renal effects after ethylene glycol ingestion typically occur during the third stage of ethylene glycol toxicity, 24–72 hours after acute exposure (Davis et al. 1997; Hess et al. 2004).  
- Kidney damage manifests as acute oliguric renal failure.  
- The most common physical finding is costovertebral angle tenderness (Friedman et al. 1962).  
- The most characteristic abnormality is the presence of large numbers of “tent-shaped” (octahedral) or needle-shaped oxalate crystals in the urine (Froberg et al. 2006; Hantson et al. 2002; Huhn and Rosenberg 1995; Leth and Gregersen 2005; McMartin K 2009; Olivero 1993; Takayesu et al. 2006).  
- Absence of oxalate crystals does not rule out an ethylene glycol poisoning diagnosis (Baum et al. 2000; Boyer et al. 2001; Curtin et al. 1992; Hantson et al. 2002; Haupt et al. 1988). |
Other typical urinalysis abnormalities include the following:

- Low specific gravity
- Proteinuria
- Microhematuria
- Pyuria

Renal dysfunction might be mild and short-lived or severe and persistent. Although uncommon, permanent renal insufficiency does occur (Berman et al. 1957; Buell et al. 1998; Friedman et al. 1962; Hantson et al. 1998; Parry and Wallach 1974; Takayesu et al. 2006).

The toxicity of ethylene glycol is linked with all four metabolites.

- Glycolic acid contributes to the metabolic acidosis.
- Oxalic acid is poorly soluble in the presence of calcium.
  - Calcium oxalate crystals in the urine are supportive of the diagnosis.
  - The precipitation of oxalate crystals in the tubular lumen leads to luminal blockage and compression-induced loss of glomerular filtration (renal failure).
  - In transformed kidney cells, the oxalate ion induces cytotoxic damage (McMartin KE and Cenac 2000).
- Glycoaldehyde and glyoxylate might be responsible for ethylene glycol nephrotoxicity (Poldelski et al. 2001).

### Carcinogenicity

Studies in humans and animals have not shown any associations between ethylene glycol exposure and the incidence of any cancer (ATSDR 2014).

### Developmental and Reproductive Effects

No known human studies have evaluated a link between ethylene glycol exposure and reproductive or developmental hazards in humans (ATSDR 2014).
- Ethylene glycol exposure was teratogenic to mice and rats, resulting in craniofacial and neural tube closure defects and skeletal dysplasia [Lamb et al. 1985; Marr et al. 1992; Price et al. 1985; Tyl et al. 1995].
- Large oral doses of ethylene glycol (>500 mg kg\(^{-1}\) in mice and >1,000 mg kg\(^{-1}\) in rats) might cause developmental toxicity in those animals, including
  - axial skeletal malformations,
  - reduced body weights,
  - external malformations, and
  - increased post-implantation loss [IPCS 2002; NTP-CERHR 2004].

| Other Effects | Nausea, vomiting (with or without blood), and abdominal pain often occur soon after ethylene glycol ingestion (Davis et al. 1997; Johnson et al. 1999; Moossavi et al. 2003; Singh et al. 2001; Verrilli et al. 1987). Ethylene glycol is only a minor skin and mucous membrane irritant, although a few patients have had allergic contact dermatitis (Clayton GD & Clayton FE 1994). Reported effects on the blood have included (Hantson et al. 1998; Rasic et al. 1999; Verrilli et al. 1987)
  - leukocytosis,
  - methemoglobinemia (rare), and
  - bone marrow arrest.
  Reported musculoskeletal effects have included
  - muscle tenderness and
  - elevation of creatine kinase (Friedman et al. 1962; Parry and Wallach 1974; Verrilli et al. 1987). |

| Key Points | After ethylene glycol ingestion, signs of inebriation are among the first manifestations.
Unmetabolized ethylene glycol causes CNS depression. Delays in initiating treatment can result in more severe adverse effects.
The most common cause of tachypnea is uncompensated metabolic acidosis. |
- Ethylene glycol poisoning through ingestion can cause noncardiogenic pulmonary edema and ARDS.
- Ethylene glycol poisoning can cause dysrhythmias and heart failure.
- Ethylene glycol toxicity is characterized by an osmolal gap and metabolic acidosis with an elevated anion gap.
- Nephrotoxicity after ethylene glycol ingestion typically occurs 24-72 hours after acute exposure.
- No studies were located that link ethylene glycol exposure to cancer or reproductive or developmental hazards in humans.

10. The metabolic acidosis of ethylene glycol poisoning is characterized as which of the following?

A. Normochloremic.
B. Low bicarbonate level and pH.
C. Acidemia and elevated anion gap.
D. All of the above.

11. Which of the following statements best characterizes nephrotoxicity resulting from significant ethylene glycol poisoning?

A. Kidney damage manifests as acute oliguric renal failure.
B. Urine contains many oxalate crystals.
C. Absence of oxalate crystals in the urine does not rule out a diagnosis of ethylene glycol poisoning.
D. All of the above.

7. The best choice is D. All of the above. The main toxicity of ethylene glycol results from its conversion in the liver to acid and aldehyde metabolites. The latter inhibits many cellular biochemical reactions, including oxidative phosphorylation and cellular respiration, glucose and serotonin metabolism, protein synthesis, DNA replication, and ribosomal RNA formation.

Feedback for A. (Web only): The best choice is D. All of the above. The main toxicity of ethylene glycol results from its conversion in the liver to acid and aldehyde metabolites. The latter inhibits many cellular biochemical reactions, including oxidative phosphorylation and cellular respiration, glucose and serotonin metabolism, protein synthesis, DNA replication, and ribosomal RNA formation.

Feedback for B. (Web only): The best choice is D. All of the above. The main toxicity of ethylene glycol results from its conversion in the liver to acid and aldehyde metabolites. The latter inhibits many cellular biochemical reactions, including oxidative phosphorylation and cellular respiration, glucose and serotonin metabolism, protein synthesis, DNA replication, and ribosomal RNA formation.
serotonin metabolism, protein synthesis, DNA replication, and ribosomal RNA formation.

Feedback for C. (Web only): The best choice is D. All of the above. The main toxicity of ethylene glycol results from its conversion in the liver to acid and aldehyde metabolites. The latter inhibits many cellular biochemical reactions, including oxidative phosphorylation and cellular respiration, glucose and serotonin metabolism, protein synthesis, DNA replication, and ribosomal RNA formation.

Feedback for D. (Web only): Correct. All of the above. The main toxicity of ethylene glycol results from its conversion in the liver to acid and aldehyde metabolites. The latter inhibits many cellular biochemical reactions, including oxidative phosphorylation and cellular respiration, glucose and serotonin metabolism, protein synthesis, DNA replication, and ribosomal RNA formation.

To review relevant content, see “Mechanism of Toxicity” in this section.

8. The best choice is B. The initial phase of ethylene glycol poisoning is characterized by inebriation caused by unmetabolized ethylene glycol.

Feedback for A. (Web only): The best choice is B. The initial phase of ethylene glycol poisoning is characterized by inebriation caused by unmetabolized ethylene glycol. Ethanol is not part of ethylene glycol metabolism.

Feedback for B. (Web only): Correct. The initial phase of ethylene glycol poisoning is characterized by inebriation caused by unmetabolized ethylene glycol.

Feedback for C. (Web only): The best choice is B. The initial phase of ethylene glycol poisoning is characterized by inebriation caused by unmetabolized ethylene glycol. The metabolites of ethylene glycol are associated with the main toxic effects, including kidney damage.
Feedback for D. (Web only): The best choice is B. The initial phase of ethylene glycol poisoning is characterized by inebriation caused by unmetabolized ethylene glycol.

To review relevant content, see “Neurologic Effects” in this section.

9. The best choice is A. Tachypnea, hyperventilation, and Kussmaul respirations often occur 12 hours or more after exposure in victims of severe ethylene glycol poisoning. Tachypnea seen with ethylene glycol toxicity most often reflects physiological compensation for severe metabolic acidosis rather than primary lung disease or ARDS.

Feedback for A. (Web only): Correct. Tachypnea, hyperventilation, and Kussmaul respirations often occur 12 hours or more after exposure in victims of severe ethylene glycol poisoning. Tachypnea seen with ethylene glycol toxicity most often reflects physiological compensation for severe metabolic acidosis rather than primary lung disease or ARDS. The most common cause of tachypnea is uncompensated metabolic acidosis.

Feedback for B. (Web only): The best choice is A. Tachypnea, hyperventilation, and Kussmaul respirations often occur 12 hours or more after exposure in victims of severe ethylene glycol poisoning. Tachypnea seen with ethylene glycol toxicity most often reflects physiological compensation for severe metabolic acidosis rather than primary lung disease or ARDS.

Feedback for C. (Web only): The best choice is A. Pulmonary edema and adult respiratory distress syndrome (ARDS) have been reported in ethylene glycol victims. Tachypnea, however, is most likely one of the effects that reflects physiological compensation for severe metabolic acidosis.

Feedback for D. (Web only): The best choice is A. Tachypnea often occurs 12 hours or more after exposure in victims of severe ethylene glycol poisoning. It most often reflects physiological compensation for
severe metabolic acidosis rather than primary lung disease or adult respiratory distress syndrome (ARDS).

To review relevant content, see "Respiratory Effects" in this section.

10. The best choice is D. All of the above. The metabolic acidosis of ethylene glycol poisoning is characterized as normochloremic, with low bicarbonate level and pH, and acidemia with an elevated anion gap.

Feedback for A. (Web only): The best choice is D. All of the above. Although the metabolic acidosis of ethylene glycol poisoning is characterized as normochloremic, it is also characterized as having a low bicarbonate level and pH, and acidemia with an elevated anion gap.

Feedback for B. (Web only): The best choice is D. All of the above. Although the metabolic acidosis of ethylene glycol poisoning is characterized as having a low bicarbonate level and pH, it is also characterized as normochloremic with acidemia and an elevated anion gap.

Feedback for C. (Web only): The best choice is D. All of the above. Although the metabolic acidosis of ethylene glycol poisoning is characterized as having acidemia with an elevated anion gap, it is also characterized as normochloremic with a low bicarbonate level and pH.

Feedback for D. (Web only): Correct. All of the above. The metabolic acidosis of ethylene glycol poisoning is characterized as normochloremic, with low bicarbonate level and pH, and acidemia with an elevated anion gap.

To review relevant content, see "Metabolic Effects" in this section.

11. The best choice is D. All of the above. Kidney damage after ethylene glycol ingestion typically occurs 24-72 hours after acute exposure and manifests as acute oliguric renal failure. Often many tent-shaped or needle-shaped oxalate crystals are seen in the urine.
However, absence of oxalate crystals does not rule out the diagnosis of ethylene glycol poisoning.

Feedback for A. (Web only): The best choice is D. All of the above. Kidney damage after ethylene glycol ingestion typically occurs 24-72 hours after acute exposure and manifests as acute oliguric renal failure. Often many tent-shaped or needle-shaped oxalate crystals also are seen in the urine. However, absence of oxalate crystals does not rule out the diagnosis of ethylene glycol poisoning.

Feedback for B. (Web only): The best choice is D. All of the above. Although many of tent-shaped or needle-shaped oxalate crystals often are seen in the urine, absence of oxalate crystals does not rule out the diagnosis of ethylene glycol poisoning. In addition, kidney damage manifests as acute oliguric renal failure.

Feedback for C. (Web only): The best choice is D. All of the above. Absence of oxalate crystals in the urine does not rule out the diagnosis of ethylene glycol poisoning. However, many tent-shaped or needle-shaped oxalate crystals often are seen in the urine. In addition, kidney damage manifests as acute oliguric renal failure.

Feedback for D. (Web only): Correct. All of the above. Kidney damage after ethylene glycol ingestion typically occurs 24-72 hours after acute exposure and manifests as acute oliguric renal failure. Often many tent-shaped or needle-shaped oxalate crystals are seen in the urine. However, absence of oxalate crystals does not rule out the diagnosis of ethylene glycol poisoning.

Clinical Assessment—History and Physical Examination

<table>
<thead>
<tr>
<th>Learning Objective</th>
<th>After completing this section, you will be able to</th>
</tr>
</thead>
</table>
- describe what is included in the initial history and physical examination of patients potentially exposed to ethylene glycol, and
- describe how the clinical presentation changes over time.

### Introduction

Ethylene glycol ingestion is a medical emergency requiring prompt recognition and aggressive treatment.

- The clinical presentation changes over time as intoxication progresses.
- Signs and symptoms depend on the amount of ethylene glycol ingested and concurrent use of alcohol.

Therefore, making a correct diagnosis requires a reliable history of the

- time,
- route, and
- intensity of exposure.

In some cases, the patient’s altered mental state can make a detailed history difficult to obtain. Begin appropriate treatment while waiting for laboratory confirmation if ethylene glycol poisoning is strongly suspected (Howland 2015; Johnson et al. 1999; Shah 2013; Stokes and Aueron 1980).

### Patient History

- An exposure history* should be part of the patient history. If you suspect a temporal association between symptoms and exposure to certain products, try to identify the specific chemical ingredients involved.

  (*ATSDR has developed other CSEMs, including “Taking an Exposure History” and “Taking a Pediatric Exposure History.” To view these CSEMs, go to [http://www.atsdr.cdc.gov/csem/](http://www.atsdr.cdc.gov/csem/).)

- In all suspected ethylene glycol poisonings, a careful history of possible substance abuse should be taken and a meticulous search in the home should be made for ethylene glycol-containing
compounds.

- A history of alcohol use might suggest ingestion of ethylene glycol as an alcohol substitute. Teens might experiment with this compound.

- Regional poison control centers often can assist in identifying the contents of bottles and packages if product labels do not list the chemical ingredients.

- Asking about similar symptoms in family members, pets, friends, and coworkers might be helpful in identifying a common source of exposure.

- Clarify when the ingestion occurred and whether ethanol also was ingested. Most serious poisonings occur from ingestion. Inhalation and dermal exposures rarely cause toxicity. In the absence of treatment, ingestion of approximately 1 g/kg of ethylene glycol is considered lethal. Product labels rarely provide the concentrations of toxic alcohols. As an approximate guide, a 50% v/v solution contains 0.6 g/mL of ethylene glycol (Sivilotti 2018).

### Physical Examination

A brief initial screening examination, including vital signs, mental status, and pupils, should be performed to identify immediate measures required to stabilize the patient (Sivilotti 2018). The mental status, vital signs, and pupillary examination are the most useful elements. They provide information to classify the patient as being in a state of physiologic excitation or depression (Rhyee 2018; Velez L.I. 2017).

The onset of ethylene glycol toxicity is delayed when ethanol also is ingested. The possibility of concomitant ethanol and toxic alcohol ingestion must be considered (Sivilotti 2018).

A mental status examination includes evaluation of alertness, orientation, cognition, and short-term memory. Peripheral nerve function is evaluated by assessing proprioception, deep tendon reflexes, motor
<table>
<thead>
<tr>
<th>Symptoms and Signs</th>
<th>strength, postural stability (Romberg test), and cutaneous sensitivity to vibration, light touch, and pin prick (Fiedler 2007).</th>
</tr>
</thead>
</table>

The time course for each stage and the severity of illness depend on the amount of ethylene glycol the patient ingested and whether the patient also ingested ethanol. Individual patients might develop any combination of organ or systemic effects (Table 2).

**Stage 1 (CNS depression phase)**

CNS depression begins soon after exposure, lasting for up to 12 hours after ingestion. This depression appears similar to ethanol intoxication, but without the characteristic odor of alcohol. The inebriation, euphoria, slurred speech, and lethargy result from unmetabolized ethylene glycol.

After glycoaldehyde forms (at 4–12 hours) and metabolic acidosis begins, CNS depression — especially in cases with high-dose exposures — can lead to the following effects:

- Nausea and vomiting
- Seizures
- Coma
- Cerebral edema (in some cases)

An osmolal gap without metabolic acidosis might be seen before significant metabolism of ethylene glycol occurs. As ethylene glycol is metabolized, the osmolal gap, if present, will decrease and an anion gap metabolic acidosis will evolve. Patients seen by a healthcare provider longer after exposure might have renal failure with normal osmolal and anion gaps and no acidosis or measurable ethylene glycol levels (Ford M 1991).

Signs of metabolic acidosis caused by the metabolites might become apparent late in stage 1.
## Stage 2 (Cardiopulmonary toxicity phase)

The following cardiorespiratory symptoms might appear 12–24 hours after ingestion:

- Tachycardia
- Tachypnea
- Hypertension or hypotension

The following conditions might develop in this stage:

- Pulmonary edema
- Pneumonitis
- Congestive cardiac failure
- Shock

Formation of oxalic acid might lead to deposition of calcium oxalate crystals in the

- meninges,
- blood vessel walls,
- lung, and
- myocardium.

These crystal deposits can cause tissue injury and can lead to hypocalcemia secondary to calcium oxalate precipitation. Most deaths from ethylene glycol poisoning occur during stage 2.

## Stage 3 (Renal toxicity phase)

Kidney damage usually develops 24–72 hours after exposure. Acidosis and acute renal failure might result from deposition of calcium oxalate crystals in the kidneys (McMartin K 2009).

The following conditions characterize the third phase:

- Flank pain
- Costovertebral angle tenderness
- Oliguric renal failure
Prolonged, rarely permanent, kidney failure is distinguished by

- proteinuria,
- hematuria,
- crystalluria, and
- increased serum BUN and creatinine.

Calcium oxalate crystals might appear in the urine soon after exposure, but absence of these crystals does not rule out ethylene glycol poisoning.

Patients might experience delayed (days to weeks after ingestion) neurological deficits. Cranial nerve deficits have occurred after ethylene glycol poisoning — an outcome likely associated with better survival rates. Severe ethylene glycol poisoning was often fatal before widespread use of hemodialysis (Rahman et al. 2012).

Clinical Assessment—Laboratory Tests

<table>
<thead>
<tr>
<th>Learning Objectives</th>
<th>After completing this section, you will be able to</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• identify the abnormal laboratory findings associated with ethylene glycol poisoning, and</td>
</tr>
</tbody>
</table>
- list three measurements that can assist with diagnosis of ethylene glycol poisoning.

**Introduction**

Ethylene glycol is a relatively common cause of overdose treated in U.S. emergency departments. Among the thousands of cases of ethylene glycol poisoning reported in the United States each year, several deaths occur.

Timely and accurate measurement of ethylene glycol is vital to establish the correct diagnosis.

**Serum Analysis**

Diagnosis of ethylene glycol poisoning usually depends on the detection of the toxicant or toxic metabolites in serum or plasma. The most commonly used analytic methods for detection and quantification of ethylene glycol use gas chromatography (GC) coupled to flame ionization detection (FID) or mass spectrometric detectors [Juenke et al. 2011]. However, many hospitals do not have this testing capacity. In fact, in many hospitals these are only available as “send out” tests, so results arrive too late for meaningful clinical decision making (Goldfrank LR et al 2019).

An elevated serum level of ethylene glycol confirms ethylene glycol poisoning. Significant toxicity is often associated with levels greater than 25 milligrams per deciliter (mg/dL) (Goldfrank LR FN 1998; Hall AH 1992). However, potentially toxic serum concentrations of ethylene glycol (≥20–30 mg/dL) do not always produce early symptoms in children or adults. Therefore, the lack of symptoms does not exclude a potentially toxic ingestion (Caravati et al. 2005).
### False Positives

Communication with the laboratory is critical in poisoning cases for several reasons:

- 2,3-butanediol, often found in the plasma of alcoholics, mistakenly can be identified as ethylene glycol when the analysis is performed by gas chromatography (Jones AW et al. 1991).
- Propylene glycol can interfere with some ethylene glycol assays (Apple et al. 1993; Hilliard et al. 2004; Robinson et al. 1983).
- Laboratory results can show an inherited metabolic disorder as ethylene glycol intoxication [(Pien et al. 2002).
- Some blood gas analyzers might mistake elevated serum glycolic acid as elevated lactic acid, leading to a false positive lactic acid result (Marwick et al. 2012; Meng et al. 2010).

### Routine Tests

All patients with known or suspected ethylene glycol ingestion require the following tests:

- Arterial or venous blood gas
- Blood glucose
- Serum electrolytes (including calcium and magnesium)
- Blood urea nitrogen (BUN) and creatinine
- Liver function tests
- Serum acetaminophen and salicylate concentrations
- Urinalysis with microscopic evaluation for crystals
- Blood ethanol
- Measured serum osmolality (sample must be obtained from the same blood draw used to obtain serum electrolytes)
- Samples for a serum volatile acid screen (which will test for methanol and isopropanol) and serum ethylene glycol should also be collected and sent. Note that many hospitals must send these samples to a reference laboratory, and results are not usually available in time to guide initial clinical management. Check with your hospital’s laboratory for specific instructions on how to order these necessary tests.
| **Ethanol, Methanol, Ketoacidosis** | A blood or serum ethanol level will establish whether ethanol is contributing to the initial CNS symptoms. If present, ethanol will substantially affect metabolism and influence therapy. Patients who have suspected ethylene glycol exposure also should be assessed with serum methanol tests. If alcoholic ketoacidosis is suspected, serum lactate and β-hydroxybutyrate levels might help identify alcoholic patients. |
| **Anion and Osmolal Gaps** | The presence of metabolic acidosis with anion and osmolal gaps is an important clue to the diagnosis (Friedman et al. 1962; Parry and Wallach 1974; Szerlip 1999). Numerous toxic substances are associated with an elevated anion gap (Table 3) (Goldfrank LR FN 1998). An elevated osmolal gap suggests the presence of a low-molecular weight substance. A measured osmolality by the freezing point depression method is needed to detect an osmolal gap. Results of this test are used to calculate the osmolal gap (Figure 2). Metabolic acidosis might be inhibited or delayed when large quantities of ethanol and ethylene glycol are ingested concurrently. In such cases, an elevated anion-gap metabolic acidosis will take longer to develop than if ethylene glycol alone were ingested. This is because aldehyde dehydrogenase (ADH) has a higher affinity for ethanol than for ethylene glycol. The presence of ethanol delays the metabolism of ethylene glycol to its acidic metabolites. An osmolal gap is often cited as indirect evidence of an exogenous alcohol or glycol, but other substances or conditions also can cause an increased osmolal gap. Conversely, failure to find an elevated osmolal gap might lead to a wrong assumption that no exogenous substances are present. Even a small osmolal gap might represent a significant ethylene glycol level. The point is, use caution when interpreting the osmolal gap. Recent reviews have argued that using the osmolal gap as a screening tool for ethylene glycol has |
significant limitations and remains hypothetical (Glaser 1996; Koga et al. 2004; Purssell et al. 2004).
| **Urinary Crystals** | Calcium oxalate or hippurate crystals in the urine, together with an elevated anion gap or osmolal gap, strongly suggest ethylene glycol poisoning (Albertson 1999). Urinary crystals result from

- the precipitation of calcium by the oxalic acid metabolite of ethylene glycol, and
- the reaction of the glycine metabolite with benzoic acid, which forms hippuric acid.

Urinary crystals can take many forms:

- Dumbbells
- Envelopes
- Needles (most commonly) (Jacobsen et al. 1988).

Absence of urinary crystals, however, does not rule out poisoning. Many studies have shown that renal damage can occur after ethylene glycol ingestion, without deposition of calcium oxalate crystals in the kidney (Hall AH 1992; Vale 1979).

| **Urine Fluorescence** | Urine from an exposed person might fluoresce under a Wood’s lamp because some antifreeze products contain fluorescein. Still, false positives and negatives often occur. An expert panel has concluded that using an out-of-hospital ultraviolet light to diagnose ethylene glycol ingestion by urine fluorescence is unreliable and contraindicated (Caravati et al. 2005). |

Adapted from (Goldfrank LR FN 1998).

**Figure 2. Formulas for calculating anion and osmolal gaps.**
*(Goldfrank LR 2015)*
An ethylene glycol level (in mg/dL) might be estimated from the osmolal gap (OG) if it is the only osmotically active poison present and levels are taken early in the course. This is most accurate if the ethylene glycol level is between 50 to 100 mg/dL:

Estimated ethylene glycol level = OG × 6.2.

The serum anion gap (AG) is determined from serum electrolytes measured in mEq/L and is be defined by the formula:

\[ \text{AG} = (\text{Na}^+ + \text{K}^+) - (\text{Cl}^- + \text{HCO}_3^-) \]

(Normal anion gap: 12–16)

The serum osmolal gap (OG) is most commonly approximated by the formula:

\[ \text{OG} = \text{osmolality (measured)} - 2\text{Na}^+ + [\text{BUN divided by 2.8}] + [\text{glucose divided by 18}] + [\text{BAT (ethanol) divided by 4.6 (if present)}] \]

(Normal osmolal gap: −14 to +10)

* In this formula, osmolality (measured) is obtained by the freezing point–depression method and expressed in milliosmoles per liter (mOsm/L): Na\(^+\) in mEq/L, BUN and glucose in mg/dL, blood alcohol test (BAT) in mg/dL.

### Key Points

- Ethylene glycol poisoning is strongly suggested by
  - an elevated anion-gap metabolic acidosis,
  - an elevated osmolal gap, and
  - urinary calcium oxalate or hippuric acid crystals.

- Measurement of serum ethylene glycol levels can confirm poisoning.

### Progress Check

15. Which of the following is the most reliable diagnostic index for suspected ethylene glycol ingestion?

   A. An elevated anion gap and an increased osmolal gap.
   B. Normochloremic metabolic acidosis.
   C. Calcium oxalate or hippurate crystalluria.
   D. Elevated serum ethylene glycol level.
15. The best choice is D. The presence of metabolic acidosis (answer B) with anion and osmolal gaps (answer A) are important clues to the diagnosis. However, numerous toxic substances are associated with an elevated anion gap (Table 3). Numerous studies have documented that renal damage occurs after ethylene glycol ingestion, even without deposition in the kidney of calcium oxalate crystals (answer C). Although answers A, B, and C together strongly suggest ethylene glycol poisoning, elevated serum ethylene glycol level remains the most reliable diagnostic index. At the time of testing for ethylene glycol poisoning, all, some, or none of the findings in answers A, B, or C might be present.

Feedback for A. (Web only): The best choice is D. The presence of anion and osmolal gaps are important clues to the diagnosis. However, numerous toxic substances are associated with an elevated anion gap (Table 3). Although an elevated anion gap and an increased osmolal gap strongly suggest ethylene glycol poisoning, an elevated serum ethylene glycol level is the most reliable diagnostic index.

Feedback for B. (Web only): The best choice is D. The presence of normochloremic metabolic acidosis is an important clue to the diagnosis. However, numerous toxic substances are associated with metabolic acidosis (Table 3). Thus, an elevated serum ethylene glycol level is the most reliable diagnostic index.

Feedback for C. (Web only): The best choice is D. Numerous studies have documented that renal damage occurs after ethylene glycol ingestion, even without deposition of calcium oxalate crystals in the kidney. Although calcium oxalate or hippurate crystalluria strongly suggests ethylene glycol poisoning, an elevated serum ethylene glycol level is the most reliable diagnostic index.

Feedback for D. (Web only): Correct. The presence of metabolic acidosis (answer B) with anion and osmolal gaps (answer A) are important clues to the diagnosis. However, numerous toxic substances are associated
with an elevated anion gap (Table 3). Numerous studies have documented that renal damage occurs after ethylene glycol ingestion, even without deposition in the kidney of calcium oxalate crystals (answer C). Although answers A, B, and C together strongly suggest ethylene glycol poisoning, an elevated serum ethylene glycol level remains the most reliable diagnostic index. At the time of testing for ethylene glycol poisoning, all, some, or none of the findings in answers A, B, or C might be present.

# How Should Patients Exposed to Ethylene Glycol Be Treated and Managed?

<table>
<thead>
<tr>
<th>Learning Objectives</th>
<th>After completing this section, you will be able to describe treatment strategies for managing ethylene glycol poisoning cases.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduction</strong></td>
<td>Treatment should not be delayed pending results of ethylene glycol serum levels if the patient’s condition or history suggests such poisoning. Treatment advice can be obtained from a regional poison control center or medical specialists such as the following with expertise and experience treating patients exposed to ethylene glycol:</td>
</tr>
<tr>
<td></td>
<td>- Board-certified occupational and environmental medicine physicians</td>
</tr>
<tr>
<td></td>
<td>- Board-certified pediatric environmental health specialists</td>
</tr>
<tr>
<td></td>
<td>- Board-certified medical toxicologists</td>
</tr>
<tr>
<td><strong>Supportive Care</strong></td>
<td>For initial patient stabilization, the clinician should first assess and secure the patient's airway, breathing, and circulation.</td>
</tr>
<tr>
<td><strong>Gastrointestinal Decontamination</strong></td>
<td>Gastrointestinal decontamination measures, such as activated charcoal, gastric lavage, and gastric aspiration, provide little benefit in ethylene glycol poisoning because ethylene glycol is rapidly absorbed (Sivilotti 2018).</td>
</tr>
<tr>
<td><strong>Specific Treatment</strong></td>
<td>Specific treatment for ethylene glycol poisoning may include the following:</td>
</tr>
<tr>
<td></td>
<td>- Sodium bicarbonate to temporarily correct the metabolic acidosis, as indicated</td>
</tr>
<tr>
<td></td>
<td>- Fomepizole or ethanol to competitively inhibit metabolism of ethylene glycol to its more toxic metabolites (Baud et al. 1988; Brent et al. 1999; Jones AL and Volans 1999; Sivilotti 2018)</td>
</tr>
<tr>
<td></td>
<td>- If indicated, hemodialysis to remove ethylene glycol and glycolic acid (Bey et al. 2002; Cheng et al.)</td>
</tr>
</tbody>
</table>
The above treatment strategies are effective in most cases, but if treatment is delayed, renal failure and death can occur (Leth and Gregersen 2005; Pellegrino et al. 2006).

| **Fomepizole Therapy** | Fomepizole, an alcohol dehydrogenase enzyme (ADH) antagonist, is the preferred therapy for ethylene glycol poisoning. The American Academy of Clinical Toxicology developed the following criteria for using fomepizole rather than ethanol (Barceloux et al. 1999):

- Ingestion of multiple substances, resulting in depressed level of consciousness
- Altered consciousness
- Lack of adequate intensive care staffing or laboratory support to monitor ethanol administration
- Relative contraindications to ethanol
- Critically ill patient with an anion-gap metabolic acidosis of unknown origin and potential exposure to ethylene glycol
- Patients with active hepatic disease |

| **Advantages of Fomepizole Therapy** | Fomepizole therapy might obviate the need for hemodialysis in the absence of renal insufficiency and significant metabolic acidosis (Battistella 2002; Borron et al. 1999; Brent 2001; Bronstein et al. 2009; Druteika et al. 2002; Harry et al. 1998; Harry et al. 1994; Watson 2000).

In comparison with ethanol (Lepik et al. 2009), fomepizole

- is easier to use clinically and requires less monitoring,
- has a slower rate of elimination,
- has a longer duration of action,
- has a reasonable dosing schedule,
- has less potential for adverse effects, |
- is easier to administer,
- results in shorter hospital stays,
- has more predictable and prolonged results, and
- does not cause central nervous system (CNS) depression or hypoglycemia.

<table>
<thead>
<tr>
<th>Ethanol Therapy</th>
</tr>
</thead>
<tbody>
<tr>
<td>If fomepizole is unavailable or the patient has a known allergy, alcohol dehydrogenase can be blocked with 10 mL/kg of a 10% ethanol solution, followed by 1 mL/kg of 10% ethanol solution infused per hour. Titrate to a serum ethanol concentration of 100 mg/dL (Sivilotti 2018). The disadvantages of ethanol are that it</td>
</tr>
<tr>
<td>requires continuous administration and frequent monitoring of serum ethanol and glucose levels,</td>
</tr>
<tr>
<td>can cause CNS depression and hypoglycemia, and</td>
</tr>
<tr>
<td>poses problems in patient care, such as drunkenness.</td>
</tr>
<tr>
<td>Although ethanol costs much less, the savings might be offset by additional costs for</td>
</tr>
<tr>
<td>monitoring the patient,</td>
</tr>
<tr>
<td>laboratory tests, and</td>
</tr>
<tr>
<td>hemodialysis for some patients.</td>
</tr>
</tbody>
</table>
**Hemodialysis**

Hemodialysis can rapidly remove toxic acid metabolites and parent alcohols. Several studies (Barceloux et al. 1999; Brent et al. 1999; Jammalamadaka and Raissi 2010; Sivilotti 2018) suggest considering hemodialysis when

- serum ethylene glycol levels exceed 50 mg/dL (8.1 mmol/L),
- severe acidemia (pH <7.25) or fluid/electrolyte disturbances persist despite ethanol or fomepizole therapy,
- vital signs continue to deteriorate despite intensive supportive treatment, or
- renal failure develops.

Continue hemodialysis until

- acidosis is controlled, and
- serum ethylene glycol level falls below 20 mg/dL.

When renal function is preserved, patients often can be treated without hemodialysis. This outcome underscores the effectiveness of supportive care and the use of fomepizole in the treatment of ethylene glycol poisoning, even at levels that have traditionally required hemodialysis (Buchanan et al. 2010; Levine et al. 2012; Velez L. I. et al. 2007).

**Vitamin Treatment**

Thiamine and pyridoxine are two water-soluble B-complex vitamins that act as metabolic cofactors in the metabolism of ethylene glycol. The benefits of giving supplemental thiamine (100 mg IV) or pyridoxine (50 mg IV) to patients poisoned with ethylene glycol are unknown. However, both are routinely administered, particularly if the patient's nutritional status is suspect (Sivilotti 2018).

**Pediatric Cases**

For those pediatric patients who do show signs of ethylene glycol poisoning, the diagnostic and treatment considerations described above for adults largely apply. The limited published experience with fomepizole
supports its safe and effective use in children at the same
dosing protocol given above
(Brent 2010; Caravati et al. 2004; Schwerk et al. 2007;
Sivilotti 2018).

**Key Points**

- Supportive care is the cornerstone of treatment of the poisoned patient.
- Because ethylene glycol is rapidly absorbed, gastrointestinal decontamination has little role in treatment.
- Fomepizole therapy might obviate the need for hemodialysis in the absence of renal insufficiency and significant metabolic acidosis.
- A regional poison control center or medical specialists with expertise and experience treating patients exposed to ethylene glycol can provide treatment advice.

**Progress Check**

16. Which of the following best describes the treatment strategy for managing patients with ethylene glycol poisoning?

   A. Sodium bicarbonate to correct the metabolic acidosis as indicated.
   B. Ethanol or fomepizole to competitively inhibit metabolism of ethylene glycol to its more toxic metabolites.
   C. Hemodialysis, if indicated, to remove ethylene glycol and glycolic acid.
   D. All of the above.

17. Which of the following IS NOT considered a current indication for hemodialysis after ethylene glycol ingestion?

   A. Severe acidemia (pH < 7.25) or fluid/electrolyte disturbances that persist despite fomepizole therapy.
   B. Vital signs continue to deteriorate despite intensive supportive treatment.
   C. Renal failure develops.
   D. A serum ethylene glycol level of 10–15 mg/dL.
### Answers

16. The best choice is D. All of the above. A treatment strategy to best manage patients with ethylene glycol poisoning includes, when indicated,

- use of sodium bicarbonate to correct metabolic acidosis,
- use of ethanol or fomepizole (antizol) to competitively inhibit the metabolism of ethylene glycol to its more toxic metabolites, and
- hemodialysis to remove ethylene glycol and glycolic acid.

This treatment strategy is effective in most cases, but if treatment is delayed, renal failure and death can occur.

Feedback for A. (Web only): The best choice is D. All of the above. A treatment strategy to best manage patients with ethylene glycol poisoning includes, when indicated, use of bicarbonate to correct metabolic acidosis. It also might include use of ethanol or fomepizole to competitively inhibit metabolism of ethylene glycol to its more toxic metabolites. Hemodialysis might be needed to remove ethylene glycol and glycolic acid.

Feedback for B. (Web only): The best choice is D. All of the above. A treatment strategy to best manage patients with ethylene glycol poisoning includes, when indicated, use of ethanol or fomepizole to competitively inhibit metabolism of ethylene glycol to its more toxic metabolites. It also might include use of bicarbonate to correct metabolic acidosis and hemodialysis to remove ethylene glycol and glycolic acid.

Feedback for C. (Web only): The best choice is D. All of the above. A treatment strategy to best manage patients with ethylene glycol poisoning includes, when indicated, hemodialysis to remove ethylene glycol and glycolic acid. It also might include use of bicarbonate to correct metabolic acidosis, and use of ethanol or fomepizole to competitively inhibit metabolism of ethylene glycol to its more toxic metabolites.
Feedback for D. (Web only): Correct. All of the above. A treatment strategy to best manage patients with ethylene glycol poisoning includes, when indicated,

- use of sodium bicarbonate to correct metabolic acidosis,
- use of ethanol or fomepizole (antizol) to competitively inhibit the metabolism of ethylene glycol to its more toxic metabolites, and
- hemodialysis to remove ethylene glycol and glycolic acid.

This treatment strategy is effective in most cases, but if treatment is delayed, renal failure and death can occur.

*To review relevant content, see “Specific Treatment” in this section.*

17. The best choice is D. Indications for hemodialysis treatment after ethylene glycol ingestion include

- severe acidemia (pH <7.25) or fluid/electrolyte disturbances that persist despite fomepizole therapy,
- vital signs that continue to deteriorate despite intensive supportive treatment, and
- development of renal failure.

Although a serum ethylene glycol level of ≥50 mg/dL was considered an indication for hemodialysis, there are reports of patients with levels of ≥50 mg/dL being successfully treated with fomepizole, with or without bicarbonate, and without hemodialysis.

Feedback for A. (Web only): The best choice is D. An indication for hemodialysis treatment after ethylene glycol ingestion is severe acidemia (pH <7.25) or fluid/electrolyte disturbances that persist despite fomepizole therapy. Indications also include vital signs that continue to deteriorate despite intensive supportive treatment, and development of renal failure. Although a serum ethylene glycol level of ≥50 mg/dL was considered an indication for hemodialysis, there are reports of patients with levels of ≥50 mg/dL being successfully
treated with fomepizole, with or without bicarbonate, and without hemodialysis.

Feedback for B. (Web only): The best choice is D. An indication for hemodialysis treatment after ethylene glycol ingestion is vital signs that continue to deteriorate despite intensive supportive treatment. Indications also include severe acidemia (pH <7.25) or fluid/electrolyte disturbances that persist despite fomepizole therapy, and development of renal failure. Although a serum ethylene glycol level of ≥50 mg/dL was considered an indication for hemodialysis, there are reports of patients with levels of ≥50 mg/dL being successfully treated with fomepizole, with or without bicarbonate, and without hemodialysis.

Feedback for C. (Web only): The best choice is D. An indication for hemodialysis treatment after ethylene glycol ingestion is development of renal failure. Indications also include severe acidemia (pH <7.25) or fluid/electrolyte disturbances that persist despite fomepizole therapy, and vital signs that continue to deteriorate despite intensive supportive treatment. Although a serum ethylene glycol level of ≥50 mg/dL was considered an indication for hemodialysis, there are reports of patients with levels of ≥50 mg/dL being successfully treated with fomepizole, with or without bicarbonate, and without hemodialysis.

Feedback for D. (Web only): Correct. Indications for hemodialysis treatment after ethylene glycol ingestion include

- severe acidemia (pH <7.25) or fluid/electrolyte disturbances that persist despite fomepizole therapy,
- vital signs that continue to deteriorate despite intensive supportive treatment, and
- development of renal failure.

Although a serum ethylene glycol level of ≥50 mg/dL was considered an indication for hemodialysis, there are reports of patients with levels of ≥50 mg/dL (ethylene glycol ≥7.5 mmol/L) being successfully treated with fomepizole, with or without bicarbonate, and without hemodialysis.

What Is Propylene Glycol?

<table>
<thead>
<tr>
<th>Learning Objective</th>
<th>After completing this section, you will be able to</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• describe the uses of propylene glycol, and</td>
</tr>
<tr>
<td></td>
<td>• explain the potential risk for propylene glycol</td>
</tr>
<tr>
<td></td>
<td>toxicity.</td>
</tr>
</tbody>
</table>
| Definition | Propylene glycol is a  
|            | • clear,  
|            | • colorless,  
|            | • viscous liquid with a faintly sweet taste.  
|            | Its chemical structure is CH₃CH[OH]CH₃OH.  
|            | ![Chemical Structure](image)
|            | Propylene glycol and ethylene glycol have similar physical properties and uses. Their chemical structures differ by only one methyl group (ethylene glycol = HOCH₂CH₂OH; propylene glycol = CH₃CH[OH]CH₂OH).  
|            | Ethylene glycol is a potent cause of acute toxicity in humans. In contrast, propylene glycol is a “generally recognized as safe” additive for foods and medications.  
|            | Most reported cases of propylene glycol toxicity have resulted from propylene glycol used as a diluent for intravenous administration of benzodiazepines (Kraut and Kurtz 2008).  
| Synonyms  | Synonyms for propylene glycol (ATSDR 1997) include  
|            | • 1,2-propanediol,  
|            | • 1,2-dihydroxypropane,  
|            | • methyl glycol, and  
|            | • trimethyl glycol.  

| **Uses** | Propylene glycol is generally recognized as safe by the Food and Drug Administration (FDA) (FDA 2017) for uses in

- food and tobacco products,
- pharmaceuticals, and
- cosmetics.

It has a wide range of other practical applications (ATSDR 2008), including use in

- deicers,
- coolants,
- antifreeze,
- heat transfer and hydraulic fluids,
- plasticizers, and
- other applications (smoke screen, smoke simulator, etc.). |

| **Sources of Exposure** | In the general population, propylene glycol exposure occurs primarily through ingestion of food and medications and through skin contact with cosmetics or topical medications. Propylene glycol is used as a solvent in cosmetics and pharmaceuticals, in various

- oral,
- injectable, and
- topical formulations.

Propylene glycol is a diluent found in many intravenous and oral drugs, including

- phenytoin,
- diazepam, and
- lorazepam.

No adverse health effects are likely to occur from normal use of these products. However, heavy use of injectable medications with propylene glycol has caused excess levels of propylene glycol in the body (Horinek et al. 2009; Louis et al. 1967; Neale et al. 2005; Seay et al. 1997; Wilson et al. 2000; Yorgin et al. 1997; Zar et al. 2007; Zosel et al. 2010). Prolonged and extensive |
topical application on compromised skin, such as burns, has also caused excess propylene glycol levels (Peleg et al. 1998).

<table>
<thead>
<tr>
<th><strong>Who Is at Risk</strong></th>
<th>Patients in intensive care, for example, might experience toxicity from either of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Prolonged dermal contact during treatment of burns (Peleg et al. 1998)</td>
</tr>
</tbody>
</table>

Patients at risk for propylene glycol toxicity (Lim et al. 2014) include the following:

- Patients with underlying kidney disease
- Patients with less effective or impaired alcohol dehydrogenase enzyme systems (e.g., children younger than 4 years, pregnant women, patients with hepatic disease, and patients treated with disulfiram or metronidazole)
- Patients with epilepsy
- Burn patients who receive extensive dermal applications of propylene glycol
Absorption of propylene glycol from the gastrointestinal tract is rapid. The maximal plasma concentrations in humans occur within 1 hour after ingestion.

**Metabolites**

Propylene glycol is metabolized in the liver by alcohol dehydrogenase to

- lactic acid, and then
- pyruvic acid.

Both of these metabolites are normal constituents of the citric acid cycle and are further metabolized to

- carbon dioxide and
- water.

About 45% of an absorbed propylene glycol dose is excreted unchanged by the kidneys or as the glucuronide conjugate.

**Half-life**

In adults with normal liver and kidney function, the terminal half-life of propylene glycol ranges from 1.4 hours to 3.3 hours (Speth et al. 1987). In contrast, the mean half-life is significantly longer in infants — 19.3 hours (range: 10.8–30.5 hours) — because of decreased renal elimination (Lim et al. 2014).

Although propylene glycol is a commonly used solvent for intravenous medications, it might become toxic when administered in large doses over a short period (Bledsoe and Kramer 2008; Zar et al. 2007). Iatrogenic propylene glycol overdose can cause the following:

- Refractory hypotension (Wilson et al. 2000)
- Arrhythmias (Louis et al. 1967)
- Hemolysis (Demey et al. 1988)
- Renal dysfunction (e.g., increased serum creatinine concentrations, proximal renal tubular cell injury, etc.) (Yaucher et al. 2003; Yorgin et al. 1997)
- Seizure, coma (Greller and Gupta 2017)

Pediatric patients also might develop CNS depression and seizures (Lim et al. 2014; O'Donnell et al. 2000).

### Clinical Evaluation

Propylene glycol toxicity should be suspected in any patient receiving medication that contains propylene glycol as a diluent or solvent and who has

- hyperosmolality,
- lactic acidosis,
- acute kidney injury, or
- a clinical scenario similar to sepsis or systemic inflammatory response syndrome (SIRS) (Zar et al. 2007).

The clinical diagnosis of propylene glycol intoxication may be difficult because many hospitals do not measure propylene glycol levels. However, the osmolar gap, anion gap, and lactate are commonly elevated in propylene glycol intoxication (Lim et al. 2014).

An osmolar gap at 48 hours after continuous infusion strongly predicts propylene glycol accumulation. An elevated anion gap and lactic acidosis are poor indicators (Arroliga et al. 2004; Barnes et al. 2006; Wilson et al. 2005; Yahwak et al. 2008; Zar et al. 2007).

An osmolar gap >10 mmoles/L suggests that the serum propylene glycol concentration is high enough to cause toxicity (Barnes et al. 2006; Tietze and Fuchs 2018; Yahwak et al. 2008).
| **Treatment** | Because this disorder is iatrogenic, prevention by limiting the dosage of propylene glycol given to patients in the intensive care unit might be the best treatment [(Kraut and Kurtz 2008). Healthcare providers should consider a 50% reduction in the maximum daily dose for patients with underlying risk factors (see discussion on “Who’s at Risk”). The maximum daily dose of drug for a pediatric patient can be extrapolated from the adult data (based on a 70-kg patient) (Lim et al. 2014).

Metabolic acidosis caused by large amounts of propylene glycol in injected medications can be treated by discontinuing the offending medication and providing sodium bicarbonate and fomepizole (Zosel et al. 2010).

In severe cases, hemodialysis is effective in correcting hyperosmolality by removing propylene glycol from the blood (Demey et al. 1988; Kraut and Kurtz 2008; Lim et al. 2014; Parker et al. 2002; Wilson et al. 2000). |
| **Standards and Regulations** | No workplace or environmental standards govern propylene glycol.

Propylene glycol is “generally recognized as safe” by the U.S. Food and Drug Administration (FDA) (FDA 2017). FDA considers an average daily dietary intake of 23 mg/kg of body weight to be safe for persons 2–65 years of age (ATSDR 2008). |
| **Key Points** | • Various foods, cosmetics, and pharmaceutical products contain propylene glycol.

• Propylene glycol is metabolized to compounds that are normal constituents of the citric acid cycle.

• Propylene glycol toxicity generally is not a factor in environmental or occupational exposures.

• Iatrogenic propylene glycol overdose is the most common cause of propylene glycol poisoning. |
- The major toxicological effects of propylene glycol poisoning include the following:
  - Hyperosmolality
  - Elevated lactate
  - Refractory hypotension
  - Arrhythmias
  - Hemolysis
  - Renal dysfunction

- Because this disorder is iatrogenic, prevention by limiting the dosage of propylene glycol given to patients in the intensive care unit might be the best treatment.

<table>
<thead>
<tr>
<th>Progress Check</th>

*To review relevant content, see “Uses” in this section.* | | 19. The best choice is D. Unlike the more toxic metabolites from ethylene glycol metabolism, propylene glycol is metabolized in the liver by alcohol dehydrogenase to lactic acid, then to pyruvic acid. Both of these metabolites are normal constituents of the citric acid cycle and are further metabolized to carbon dioxide and water.  
Feedback for A. (Web only): The best choice is D. Absorption of propylene glycol from the gastrointestinal |
Propylene glycol is metabolized in the liver by alcohol dehydrogenase to lactic acid and then pyruvic acid. Both of these metabolites are normal constituents of the citric acid cycle and are further metabolized to carbon dioxide and water.

Feedback for B. (Web only): The best choice is D. Propylene glycol is metabolized in the liver by alcohol dehydrogenase to lactic acid and then pyruvic acid. Both of these metabolites are normal constituents of the citric acid cycle and are further metabolized to carbon dioxide and water.

Feedback for C. (Web only): The best choice is D. Ethylene glycol is metabolized in the liver to more toxic metabolites. Propylene glycol is metabolized in the liver by alcohol dehydrogenase to lactic acid and then pyruvic acid. Both of these metabolites are normal constituents of the citric acid cycle and are further metabolized to carbon dioxide and water.

Feedback for D. (Web only): Correct. Unlike the more toxic metabolites from ethylene glycol metabolism, propylene glycol is metabolized in the liver by alcohol dehydrogenase to lactic acid, then to pyruvic acid. Both of these metabolites are normal constituents of the citric acid cycle and are further metabolized to carbon dioxide and water.

To review relevant content, see “Biological Fate” in this section.

20. The correct choice is C. Metabolic acidosis caused by large amounts of propylene glycol in injected medications can be treated with sodium bicarbonate and fomepizole. In severe cases, hemodialysis is effective in correcting hyperosmolality by removing propylene glycol from the blood. Propylene glycol is metabolized in the liver by alcohol dehydrogenase (ADH) to the normal constituents of the citric acid cycle. Ethanol is not needed to exhaust ADH because ADH metabolizes propylene glycol to nontoxic constituents.
Feeback for A. (Web only): The correct choice is C. Metabolic acidosis caused by large amounts of propylene glycol in injected medications can be treated with sodium bicarbonate and fomepizole. In severe cases, hemodialysis is effective in correcting hyperosmolality by removing propylene glycol from the blood. Ethanol is not needed to exhaust ADH because ADH metabolizes propylene glycol to nontoxic constituents.

Feedback for B. (Web only): The best choice is C. Metabolic acidosis caused by large amounts of propylene glycol in injected medications can be treated with sodium bicarbonate and fomepizole. In severe cases, hemodialysis is effective in correcting hyperosmolality by removing propylene glycol from the blood. Ethanol is not needed to exhaust ADH because ADH metabolizes propylene glycol to nontoxic constituents.

Feedback for C. (Web only): Correct. Propylene glycol is metabolized in the liver by alcohol dehydrogenase (ADH) to the normal constituents of the citric acid cycle. In severe cases, hemodialysis is effective in correcting hyperosmolality by removing propylene glycol from the blood. Ethanol is not needed to exhaust ADH because ADH metabolizes propylene glycol to nontoxic constituents.

Feedback for D. (Web only): The correct choice is C. Metabolic acidosis caused by large amounts of propylene glycol in injected medications can be treated with sodium bicarbonate and fomepizole. In severe cases, hemodialysis is effective in correcting hyperosmolality by removing propylene glycol from the blood. Ethanol is not needed to exhaust ADH because ADH metabolizes propylene glycol to nontoxic constituents.

# What Instructions Should You Give to Patients Regarding Ethylene Glycol/Propylene Glycol Exposure?

## Learning Objectives

After completing this section, you will be able to describe self-care and clinical follow-up instructions for patients exposed to ethylene glycol or propylene glycol.

## Introduction

- All patients with ethylene glycol poisoning should be evaluated and treated immediately.
- All patients exposed to ethylene glycol or propylene glycol need basic guidance on
  - self-care, so they can minimize further risks and avoid complications to the extent possible, and
  - clinical follow-up, so they understand when and why to return for further medical attention.

## Self-Care

Advise patients to avoid exposures and conditions that might further increase their risk for disease or worsen their existing health condition(s). You might offer the following advice to your patient:

- If you have any antifreeze in your home, keep it in original, labeled containers and securely stored and out of children’s reach.
- If you suspect that someone has ingested antifreeze, be sure he or she sees a healthcare provider immediately.

## Clinical Follow Up

Patients should be advised to consult their healthcare provider if they develop
- any sign or symptom of CNS involvement, or
• signs or symptoms of other health changes (especially those possibly related to heart and kidney problems).

ATSDR’s patient education and care instruction sheet on ethylene glycol and propylene glycol is a job aid that provides relevant follow-up instructions for patients possibly exposed to ethylene glycol or propylene glycol including follow-up instructions.

### Key Points

• Advise patients to avoid exposures and conditions that might further increase their risk for disease or worsen their existing health condition(s).
• Patients should seek immediate evaluation if they develop neurological problems or other health changes after exposure.

### Progress Check

21. Patients who have been exposed to ethylene glycol should take what action?

A. Seek clinical evaluation and treatment as soon as possible.
B. Learn how to avoid further exposure.
C. Know when to call their healthcare provider.
D. All of the above.

### Answers

21. The best choice is D: All of the above. Medical tests and treatment are available for ethylene glycol poisoning, and treatment should begin as soon as possible. The treating physician should find out whether the patient has any materials at home or work that contain ethylene glycol and advise patients to avoid exposures and conditions that might increase their risk for disease or worsen their existing health condition(s). In addition, patients should contact their physician if they develop neurological problems or other health changes.
Feedback for A. (Web only): The best choice is D. All of the above. All patients with ethylene glycol poisoning should be evaluated and treated as soon as possible. Even patients with no or mild symptoms should undergo appropriate blood and urine tests if they have a history of significant ingestion.

Feedback for B. (Web only): The best choice is D. All of the above. Advise patients to avoid exposures and conditions that might increase their risk for disease or worsen their existing health condition(s).

Feedback for C. (Web only): The best choice is D. All of the above. Patients should contact their healthcare provider if they develop neurological problems or other health changes.

Feedback for D. (Web only): Correct. Medical tests and treatment are available for ethylene glycol poisoning, and treatment should begin as soon as possible. The treating physician should find out whether the patient has any materials at home or work that contain ethylene glycol and advise patients to avoid exposures and conditions that might increase their risk for disease or worsen their existing health condition(s). In addition, patients should contact their healthcare providers if they develop neurological problems or other health changes.

Sources of Additional Information

| Ethylene Glycol and Propylene Glycol Specific Information | The following Web resources may provide more information on the adverse effects of ethylene glycol and propylene glycol, treatment of ethylene glycol and propylene glycol associated diseases, and management of persons exposed to ethylene glycol and propylene glycol. |
Agency for Toxic Substances and Disease Registry (ATSDR) [http://www.atsdr.cdc.gov]

For chemical, emergency situations

- CDC Emergency Response: 770-488-7100 and request the ATSDR Duty Officer

For chemical, non-emergency situations

- CDC-INFO [http://www.cdc.gov/cdc-info/]
- 800-CDC-INFO (800-232-4636) TTY 888-232-6348 - 24 Hours/Day
- E-mail: cdcinfo@cdc.gov

Note:

ATSDR cannot respond to questions about individual medical cases, provide second opinions, or make specific recommendations regarding therapy. Those issues should be addressed directly with your healthcare provider.

TOXFAQs for ethylene glycol (English) [http://www.atsdr.cdc.gov/toxfaqs/TF.asp?id=85&tid=21]

TOXFAQs for ethylene glycol (Spanish) [http://www.atsdr.cdc.gov/toxfaqs/TF.asp?id=85&tid=21]

ATSDR minimal response levels [http://www.atsdr.cdc.gov/mrls/index.html]

ATSDR ToxFAQs for propylene glycol (English) [http://www.atsdr.cdc.gov/toxfaqs/tf.asp?id=1121&tid=240]
General Environmental Health Information

The following Web resources provide general information on environmental health.

  
  - To view the complete library of CSEMs [http://www.atsdr.cdc.gov/csem/csem.html](http://www.atsdr.cdc.gov/csem/csem.html)

ATSDR Division of Regional Operations

Through the working relationships they have established with EPA, other federal and state agencies, individual citizens, and community groups, ATSDR regional representatives are able to maintain current and historic knowledge of the sites and issues in their regions.

Information about ATSDR’s regional offices, the states and territories that they cover, and contact information, is available at [http://www.atsdr.cdc.gov/DRO/dro_contact.html](http://www.atsdr.cdc.gov/DRO/dro_contact.html)

• The Cooperative Agreement Program provides essential support in communities nationwide to fulfill ATSDR’s mission.
• The program funds 30 states and one tribal government to develop and strengthen their abilities to evaluate and respond to environmental public health issues.

**Centers for Disease Control and Prevention (CDC)**

[http://www.cdc.gov](http://www.cdc.gov)

CDC works to protect public health and the safety of people by providing information to support health decisions. CDC also promotes health through partnerships with state health departments and other organizations.

CDC focuses national attention on developing and applying disease prevention and control (especially infectious diseases), environmental health, occupational safety and health, health promotion, prevention, and education activities designed to improve the health of the people of the United States.

**National Center for Environmental Health (NCEH)**

[http://www.cdc.gov/nceh](http://www.cdc.gov/nceh)

NCEH works to prevent illness, disability, and death from interactions between people and the environment. It is especially committed to safeguarding the health of populations that are particularly vulnerable to certain environmental hazards — children, the elderly, and people with disabilities.

NCEH seeks to achieve its mission through science, service, and leadership.

**National Institute of Health (NIH)**

A part of the U.S. Department of Health and Human Services, NIH is the primary federal agency for conducting and supporting medical research.

National Institute for Occupational Safety and Health (NIOSH) [http://www.cdc.gov/niosh/](http://www.cdc.gov/niosh/)

NIOSH is in the U.S. Department of Health and Human Services. NIOSH was established to help assure safe and healthful working conditions for workers by providing research, information, education, and training in the field of occupational safety and health.

**American College of Occupational and Environmental Medicine (ACOEM)**

ACOEM is the nation's largest medical society dedicated to promoting the health of workers through preventive medicine, clinical care, research, and education.

ACOEM members include specialists in a variety of medical practices united to develop positions and policies on vital issues relevant to the practice of preventive medicine within and outside of the workplace.

**American College of Medical Toxicologists (ACMT)**

[http://www.acmt.net](http://www.acmt.net)

ACMT is a professional, nonprofit association of physicians with recognized expertise in medical toxicology.

ACMT is dedicated to advancing the science and practice of medical toxicology through a variety of activities.

**American College of Preventive Medicine (ACPM)**

[http://www.acpm.org](http://www.acpm.org)
ACPM is the national professional society for physicians committed to disease prevention and health promotion. ACPM's 2,000 members are engaged in preventive medicine practice, teaching, and research.

**Association of Occupational and Environmental Clinics (AOEC) [http://aoec.org](http://aoec.org)**

AOEC is a network of more than 60 clinics and more than 250 individuals committed to improving the practice of occupational and environmental medicine through information sharing and collaborative research.

**Pediatric Environmental Health Specialty Units (PEHSUs) [http://www.pehsu.net](http://www.pehsu.net)**

Based at an academic center, each PEHSU is collaboration between the pediatric clinic and the AOEC occupational and environmental clinic at each site.

The PEHSUs were developed to provide education and consultation for health professionals, public health professionals, and others, about the topic of children's environmental health.

PEHSU staff members are available for consultation about potential pediatric environmental health concerns affecting the child and the family. Healthcare professionals can contact their regional PEHSU site for clinical advice.

**Poison Control Center [http://www.aapcc.org](http://www.aapcc.org)**

The American Association of Poison Control Centers supports the nation’s 55 poison centers in their efforts to prevent and treat poison exposures. Poison centers offer free, confidential medical advice 24 hours a day, seven days a week, through the Poison Help line at 1-800-222-1222. This service is a primary resource for poisoning information and helps reduce costly emergency department visits through in-home treatment.
AAPCC's mission is to actively advance the health care role and public health mission of our members through information, advocacy, education, and research.
## Posttest

**Instructions**

For each question, select the one best answer.

### Posttest

1. What are characteristics of ethylene glycol?
   - A. It is a clear, colorless, odorless, sweet-tasting liquid.
   - B. It causes acute toxicity in humans if ingested.
   - C. It is poorly absorbed by skin and has low potential for significant inhalation exposure.
   - D. All of the above.

2. Which of the following products might contain ethylene glycol?
   - A. Latex Paints.
   - B. Antifreeze.
   - C. Solvents.
   - D. All of the above.

3. Which of the following statements about ethylene glycol are true?
   - A. Inhalation is a common route of exposure because of the high vapor pressure.
   - B. Accidental or intentional ingestion accounts for most poisonings.
   - C. It is absorbed readily through intact skin.
   - D. All of the above.

4. Propylene glycol is generally recognized as safe by the Food and Drug Administration (FDA) for use in which of the following?
   - A. Food and tobacco products.
   - B. Pharmaceuticals.
   - C. Cosmetics.
   - D. All of the above.

5. After ingestion, what happens to ethylene glycol?
   - A. It is slowly absorbed by the gastrointestinal tract.
   - B. It is stored and persists in fatty tissue.
6. The first signs of ethylene glycol poisoning generally include which of the following?

A. A characteristic odor of ethanol on the breath.
B. Signs and symptoms similar to those of ethanol intoxication.
C. Cardiopulmonary signs such as tachypnea and pulmonary edema.
D. Oliguric renal failure.

7. Acute ethylene glycol exposure can adversely affect all of the following except which?

A. Lungs.
B. Heart.
C. Pancreas.
D. Kidneys.

8. Which of the following statements regarding nephrotoxicity from ethylene glycol poisoning is false?

A. Kidney damage manifests as acute oliguric renal failure.
B. Costovertebral angle tenderness is the most common physical finding.
C. Absence of oxalate crystals will rule out the diagnosis of ethylene glycol poisoning.
D. Urinalysis shows proteinuria.

9. While determining the patient’s exposure history, what additional information should you ask about?

A. A history of ethanol abuse.
B. A history of possible substance abuse.
C. Similar symptoms in family members, friends, pets, and coworkers.
D. All of the above.
10. Useful laboratory tests for diagnosing ethylene glycol poisoning include which of the following?

A. Arterial blood gases (ABG).
B. Blood glucose.
C. Blood ethanol.
D. All of the above.

11. Treatment strategies for ethylene glycol poisoning may include which of the following?

A. Sodium bicarbonate to correct the metabolic acidosis, as indicated.
B. Fomepizole to competitively inhibit metabolism of ethylene glycol to its more toxic metabolites.
C. Hemodialysis, if indicated, to remove ethylene glycol and glycolic acid.
D. All of the above.

12. What are the disadvantages of ethanol therapy?

A. It requires continuous administration and frequent monitoring of serum ethanol and glucose levels.
B. It can cause CNS depression and hypoglycemia.
C. It poses problems in patient care, such as drunkenness.
D. All of the above.

13. Treatment for acute propylene glycol poisoning might include which of the following?

A. Sodium bicarbonate therapy.
B. Administration of calcium gluconate.
C. Ethanol administration.
D. Hyperbaric oxygen.

14. Which of the following statements comparing ethylene glycol and propylene glycol are true?

A. Propylene glycol is most commonly found in foods and medicines, and ethylene glycol is found in antifreeze and other commercial products.
B. Both glycols are used for aircraft de-icing.
C. Neither compound is likely to persist for long in the environment.
D. All of the above.

**EG/PG Post-test Answers:**

1. D
2. D
3. B
4. D
5. D
6. B
7. C
8. C
9. D
10. D
11. D
12. D
13. A
14. D
