## Sources of Exposure

### General Populations
- The major sources of exposure to perfluoroalkyls, especially PFOA and PFOS, are contaminated food and drinking water.
- Industrial releases of perfluoroalkyls into ambient air or surface water may also be a source of contamination that can lead to exposure for the general population.
- The general population may also be exposed to perfluoroalkyls from carpets that have been mill treated to resist stains and from migration from paper packaging and wrapping into food and inhalation from impregnated clothes.
- Babies born to mothers exposed to PFAS can be exposed during pregnancy and while breastfeeding. However, nursing mothers should continue to breastfeed. Based on current science, the benefits of breastfeeding appear to outweigh the risks for infants exposed to PFAS in breast milk. To weigh the risks and benefits of breastfeeding, mothers should contact their doctors.

### Occupational Populations
- The production of perfluoroalkyls and use of perfluoroalkyl-containing products are sources of occupational exposure.

## Toxicokinetics and Biomonitoring Levels

### Toxicokinetics
- Limited data indicate that perfluoroalkyls are absorbed from the respiratory tract. Studies in animals suggest that many perfluoroalkyls (including PFOA and PFOS) are almost completely absorbed from the gastrointestinal tract.
- The available data suggest that perfluoroalkyls are not metabolized nor do they undergo chemical reactions in the body.
- Perfluoroalkyls are primarily excreted in the urine.
- There are substantial differences in the elimination half-lives across perfluoroalkyl compounds and animal species. The estimated elimination half-lives in humans are 2.1–10.1 years for PFOA, 3.3–27 years for PFOS, 4.7–35 years for PFHxS, 2.5–4.3 years for PFNA, 665 hours for PFBS, and 72–81 hours for PFBA. Much shorter half-lives have been estimated in experimental animals.

### NHANES Levels
- Perfluoroalkyls appear to be ubiquitous in human blood based on the widespread detection of these substances in human serum samples.
- Geometric mean serum levels of PFOA, PFOS, PFHxS, and PFNA in the U.S. population (≥12 years of age, measured 2015–2016) were 1.56, 4.72, 1.18, and 0.577 ng/mL, respectively, and other perfluoroalkyls were generally <1 ng/mL.

## Environmental Levels

### Air
- Mean PFOA levels ranged from 1.54 to 15.2 pg/m³ in urban air samples in the United States, Norway, and Japan. PFOS levels in ambient air are generally <5 pg/m³ and levels of other perfluoroalkyls are generally <1 pg/m³.

### Water
- Perfluoroalkyl levels in surface water samples are generally below 50 ng/L.

### Soil
- Background levels of perfluoroalkyls in soil and sediment have not been located.

## Biomarkers

- Measurement of serum or whole blood perfluoroalkyl concentrations is the standard accepted biomarkers of exposure to perfluoroalkyls.

## Reference
Perfluorooalkyls are Solids or Liquids

- Perfluorooalkyls are a class of anthropogenic chemicals. There are a large number of perfluorooalkyl compounds; the toxicological profile discusses 12 of these compounds.
- Perfluorooalkyls repel oil, grease, and water and have been used in surface protection products such as carpet and clothing treatments, coating for paper and cardboard packaging, and firefighting foams.
- Companies have stopped production of some perfluorooalkyls or have begun changing manufacturing practices to reduce releases and the amounts of these chemicals in their products.

Selected Perfluorooalkyl Abbreviations

- PFBA = perfluorobutyric acid
- PFBS = perfluorobutane sulfonic acid
- PFDA = perfluorodecanoic acid
- PFDoDA = perfluorododecanoic acid
- PFHpA = perfluoroheptanoic acid
- PFHxA = perfluorohexanoic acid
- PFHxS = perfluorohexane sulfonic acid
- PFNA = perfluorononanoic acid
- PFOS = perfluorooctanoic acid
- PFUnA = perfluoroundecanoic acid

Perfluorooalkyls in the Environment

- Perfluorooalkyls are very stable in the environment and are resistant to biodegradation, direct photolysis, atmospheric photooxidation, and hydrolysis.
- Perfluorooalkyls are persistent in water and soil. They are mobile in soil and leach into groundwater.
- Perfluorooalkyls biomagnify in the food web and the highest concentrations are found in apex predators. The bioaccumulation potential of perfluorooalkyls appears to increase with increasing chain length.

Routes of Exposure

- Inhalation – Most likely route of occupational exposure; minor route of exposure for the general population.
- Oral – Most likely route of exposure for the general population; food is expected to be the primary source, as well as drinking contaminated water.
- Dermal – Potential route of exposure particularly among workers who handle perfluorooalkyl-treated products.

Relevance to Public Health (Health Effects)

Health effects are determined by the dose (how much), the duration (how long), and the route of exposure.

Minimal Risk Levels (MRLs)

Inhalation

- No acute-, intermediate-, or chronic-duration inhalation MRLs were derived for perfluorooalkyls.

Oral

- No acute-duration oral MRLs were derived for perfluorooalkyls.
- Intermediate-duration (15–365 days) oral MRLs were derived for:
  - PFOA: $3 \times 10^{-6}$ mg/kg/day
  - PFOS: $2 \times 10^{-6}$ mg/kg/day
  - PFHxS: $2 \times 10^{-5}$ mg/kg/day
  - PFNA: $3 \times 10^{-6}$ mg/kg/day
- No chronic-duration oral MRLs were derived for perfluorooalkyls.

Health Effects

- A large number of studies have examined the possible relationship between levels of perfluorooalkyls in blood and adverse health effects in workers, highly exposed residents, and the general population. Although statistically significant associations have been found, the studies do not establish causality.
- The weight of evidence suggests links between perfluorooalkyl exposure and health outcomes in humans: increases in serum lipids (PFOA, PFOS, PFNA, PFDA) and pregnancy-induced hypertension and/or pre-eclampsia (PFOA, PFOS).
- The primary effects observed in animals include liver toxicity (PFOA, PFOS, PFHxS, PFNA, PFDA, PFUnA, PFBA, PFBS, PFDa, PFHpA, PFHxA), immune toxicity (PFOA, PFOS), and developmental toxicity (PFOA, PFOS, PFHxS, PFNA, PFDA, PFUnA, PFBA). There are profound differences in the toxicokinetics and mode of action of perfluorooalkyls between humans and experimental animals. Many of the observed effects in animals result through the activation of peroxisome proliferator-activated receptor α (PPAR-α). Humans are much less responsive to PPAR-α than rodents and thus may not be as susceptible to these types of effects. However, some adverse effects of perfluorooalkyls occur through PPAR-α-independent mechanisms.

Children’s Health

- Children exposed to perfluorooalkyls would be expected to experience effects similar to those expected in adults.
- Studies of children exposed to perfluorooalkyls suggest links between exposure and decreased antibody response to vaccines (PFOA, PFOS, PFHxS, PFDA), and small decreases in birth weight (PFOS, PFOS).
- Exposure from hand-to-mouth transfer from treated carpets is expected to be much greater in children.
